PREFACE

I. HISTORY OF THE ENCYCLOPAEDIA. It is only in comparatively recent years that the interdependence of the social sciences has come to be recognized as a concept necessary to their progress. The older sciences had such a great mass of phenomena to arrange and to interpret that each of them was busy in pursuing its own problems. The newer sciences found enough to do in staking out their respective fields and in vindicating their claim to existence as separate disciplines. The result was that all the sciences continued in water-tight compartments and it was thought that the greatest progress could be made by emphasizing differences rather than similarities. There was in truth much to be said for this point of view in the early years of development; but there has come a slow realization that, while there are all kinds of associations and many angles from which human contacts can profitably be studied, it is a mistake to separate them permanently into independent sections. The sentient being is after all a whole; it is unwarrantable to hold that any one phase of his activity is completely divorced from the others. Especially is this true when we consider the relation of the individual to the group and endeavor to comprehend the subtle influences reciprocally exerted by the various manifestations of common activity. The conclusions reached by the separate sciences were gradually recognized, therefore, as incomplete and provisional, and the demand went forth to attempt a better analysis through a more comprehensive synthesis.

It was in the pursuit of this purpose that after many abortive attempts and premature efforts a movement of real vitality was initiated. In the year 1923 Dr. Alexander Goldenweiser and Dr. Howard B. Woolston of the American Sociological Society sponsored a resolution designed to lead that association to consider whether the time might not have come to attempt some united action in this general direction. In the following year, as the result of the efforts of the above gentlemen and Professor W. F. Ogburn, six of the other leading learned societies in the field of social science appointed committees to consider the suggestion. An energetic campaign to enlist the interest of a wide range of scholars was carried on by Dr. Goldenweiser. A Joint Committee, consisting of three representatives of each association, held several meetings during 1925 and discussed the various possibilities from every point of view. The result of its deliberations was the recommendation that there be undertaken some comprehensive and unifying publication. The task of working out the details of the plan was entrusted to an executive committee of which the subsequent editor-in-chief was made chairman. After much discussion it was resolved to give effect to the ideas of the Joint Committee by the launching of an encyclopaedia.

During the early months of 1926 the report was adopted by each of the cooperating societies and was also approved by the Social Science Research Council. Moreover the report was sent to a small list of distinguished scholars in the various fields concerned in order to elicit their opinions as to the feasibility of the project. Uniformly favorable replies were received. These letters were printed in the *Memorandum on the Projected Encyclopaedia of the Social Sciences* published in 1927.

The executive committee then asked the chairman to serve as editor-in-chief. After much hesitation, due to his appreciation of the responsibility involved, he accepted the invitation, and devoted the next twelve months to the collection of the necessary funds and to the elaboration of the plan. By the spring of 1927 these two objectives had been attained, and in May of that year the Joint Committee was reconvened. At this meeting the number of constituent societies was increased to ten. The sponsors of the Encyclopaedia are thus the following:

- American Anthropological Association
- American Association of Social Workers
- American Economic Association
- American Historical Association
- American Political Science Association
- American Psychological Association
- American Sociological Society
- American Statistical Association
- Association of American Law Schools
- National Education Association

The time had then come for the definite organization of the enterprise. The first point was the selection of the staff. After much deliberation the editor-in-chief prevailed upon Dr. Alvin Johnson to become associate editor. Assistants well trained in the various sciences were chosen to take charge of the different fields of work and their number was increased from time to time as occasion demanded. Their names appear on the title page. Acknowledgment should also be made of the help accorded by Dr. Helen Sumner Woodbury, Miss Gladys Boone, Dr. Benjamin Ginzburg, Dr. Gustav Peck and Dr. Alexander Goldenweiser, who at various times were members of the editorial staff. The next point was the provision for the business end of the project. The enterprise was incorporated as Encyclopaedia of Social Sciences, Inc., and the corporation was composed of the Joint Committee. The Board of Directors consists of twenty-one members, eight lay and thirteen academic, the latter being selected by the constituent societies.

During the summer of 1927 the editor-in-chief went abroad in order to enlist the support of the leading European scholars. In the course of a trip which included virtually all of the important universities from Oslo to Florence, he conferred with hundreds of the most distinguished scholars scattered throughout Europe. He was both astonished and heartened by the enthusiasm that was manifested on all sides, and by the readiness of virtually everyone to lend his hearty cooperation in what was recognized to be not only a gigantic project

but one which would be of great importance to the progress of the social sciences throughout the world.

In the autumn of 1927 provision was made for the selection of a board of Advisory Editors. The members of this board were chosen by the editor-in-chief and number seventeen Americans and eleven foreigners. The advisory editors have been heavily drawn upon for constant advice and criticism, and deserve this entirely inadequate word of appreciation for their admirable services. They are not to be held responsible, however, either for the particular articles or for the selection of specific contributors. The responsibility for these matters attaches entirely to the editorial staff.

The Encyclopaedia has suffered an irreparable loss in the death of one of its advisory editors, Leonard T. Hobhouse. He placed his wealth of learning and catholicity of mind most generously at the service of the editors and they will find many occasions in the further development of the work where his advice would have been invaluable.

As the work progressed it became evident that much help would be needed by the editorial staff, in addition to that given by the advisory editors. The field covered by the Encyclopaedia was in large part so untrodden that it was resolved to enlist the aid of several hundred scholars, both here and abroad, to each of whom were referred all manner of queries as to special points falling within their competence. These specialists, whom we have designated as Editorial Consultants, have served without compensation, and to them is in large measure due whatever credit we may have earned in the difficult matter of selection and organization of material.

It had been originally intended to publish the Encyclopaedia in ten volumes. It was soon found, however, that this would necessitate either undue bulk or inordinately thin paper, so that it was finally decided to issue the work in fifteen volumes. The first volume, appearing now, will be followed in regular sequence at the rate of three volumes a year.

II. SCOPE, METHODS AND AIMS OF THE ENCYCLOPAEDIA. The Encyclopaedia includes, in the first place, all of the purely social sciences as they are described in the first section of the introduction. Obviously, however, it can not go so much into detail as would be possible for a series of works dealing with each separate science. Intensive treatment of this kind would be inappropriate because the real object of the Encyclopaedia is not so much to exhaust each particular subject as to bring out in the respective topics the relations of each science to all of the other relevant disciplines. Accordingly we endeavor to include all of the important topics in politics, economics, law, anthropology, sociology, penology and social work. With the technique of these subjects we obviously have to be more brief. A subject such as history is represented only to the extent that historical episodes or methods are of especial importance to the student of society.

In the case of what we have designated in the introduction as semi-social sciences—ethics, education, philosophy and psychology—it becomes necessary to select those topics of which the social aspects are acquiring increasing significance. This is still more true of what we have called the sciences with social implications, like biology and geography on the one hand, and medicine, philology and art on the other. It is, however, precisely the social aspects of these sciences which have come to the front in recent years and which it is especially important to emphasize. The proper treatment of the more or less outlying fields which have never yet been comprised under the head of social sciences, but which it now becomes necessary or at all events desirable to include, is one of the most difficult questions that has confronted the editors. Moreover the requirements of a work which seeks to coordinate the various social sciences and to indicate their relations to the general movement of thought involve the inclusion of many topics not usually treated in the special encyclopaedias.

In considering whether the Encyclopaedia should be primarily a dictionary or, as is customary in Germany, primarily a handbook, the decision has been reached that it ought to combine the characteristics of both. This means that the alphabetical method is followed, but that the arrangement is so flexible as to contain not only short articles of a few lines or paragraphs but also longer articles of ten or twenty thousand words, which will permit of thoroughgoing and original contributions. A carefully worked out system of cross references will enable the student with a special interest to cover thoroughly any part of the field.

It has also been decided to include biographies of deceased persons whose work has been significant in the various sciences in question. As this list will comprise many names hitherto unnoted, it has become necessary to make the typical biography very brief and to allow a longer treatment only in extraordinarily important cases. Even thus, the space allotted to biographies covers about one fifth of the entire contents.

For the sake of giving unity to the work it has been decided, largely at the suggestion of Dr. Goldenweiser, to equip it with an extended introduction, which appears in this first volume. This introduction, as will be noted, is arranged in two main divisions. In the first are a discussion of the meaning of the social sciences and a history of their development arranged according to periods. It is designed to exhibit as far as may be in non-controversial fashion the filiation of the social sciences and their contemporaneous relationship, as well as their dependence on the institutional and general intellectual situation. The second division of the introduction is an account of the social sciences as disciplines, in their historical development, throughout the world. In the final volume it is proposed to include a rigorously selected and annotated bibliography covering the works of primary importance in the development of the social sciences.

The special character of the Encyclopaedia has necessitated methods of approach which are not customary in works devoted to the separate sciences. The first task was to assemble a list of topics for the entire work, to form tentative

plans for the treatment of each topic and to assign it a space valuation. As a preliminary to this it was necessary to make a systematic analysis of each science or of each section of a science, such as the labor problem or government, and to organize this material into topics suitable for encyclopaedia treatment. A survey was made of all the existing reference books in order to note the topics treated, the methods of treatment, the relation to other topics and the allocation of space. On the basis of such data the staff prepared cards indicating the character of the article needed, the space assigned and the probable cross references. By comparison of the various topics we were able to determine how adequately each group covered its part of the field.

At the outset we classified our material as falling under the several sciences, economics, social psychology, etc., and tried to discover some rule of proportion for the distribution of space. In the actual presence of the material, classification and apportionment lost their definiteness and rigidity. Such a topic as wages, for example, may be classified as economic, but the treatment must involve the use of statistical, historical and sociological methods. David Hume may be accredited to philosophy, but he is very important for political science and economics. Psychological methods have to be employed widely in political, social and economic topics. When the Encyclopaedia has been completed, it is safe to say, no one will be able to determine what proportion of the total space has gone to one science, what proportion to another. We are trying to give each topic, wherever it falls, as adequate space as its importance and the nature of the material demand. This does not mean that the space assignment is indicative of the importance attached to the various subjects. Some very important topics can be treated adequately in relatively brief space, as, for example, the doctrine of sovereignty, which has been refined down to clear cut principles. Such a topic as housing, on the other hand, involves a great deal of specific material and requires much more space in relation to its absolute importance.

When a provisional list of topics within each field was completed it was circulated for comment and criticism among the editorial consultants. After noting their suggestions the staff prepared an outline of the contents of each article. This outline was then sent to the contributor, with the object not of limiting his freedom in any way but of pointing out our own conception of how the article would best fit into the general plan. The labor involved in this method of work has been prodigious, but the results, we hope, will prove correspondingly satisfactory.

In the history of encyclopaedia making, the problem of composition has been handled in three ways: the bulk of the work has been done by the staff; it has been assigned in large sections to editorial contributors who have sublet the actual composition to others; it has been distributed widely, each assignment being made directly from the central office. We have followed the last method, for two principal reasons. First, the importance of our enterprise consists not only in its result but also in the process of its making. Those who collaborate

with the staff in preparing the Encyclopaedia will join us in thinking through many of the problems of the relations of the sciences and of the evolution of social scientific ideas. The more we succeed in securing the cooperation of the whole body of social scientists, the greater the value to social science of the work of preparing the Encyclopaedia. Second, by distributing the work widely with especial attention to the interests of each contributor, we are justified in expecting each article to be executed according to the best ability of the writer.

In speaking of our contributors we desire to emphasize the international aspect of the enterprise. It is true that since the work is written in English the great mass of our contributors are English speaking and, since the inception of the project and its management are within the United States, the Encyclopaedia may in one sense be regarded as an American enterprise. It would be a great mistake, however, to consider it as merely a national product. Our policy has been in every case to select the scholar best fitted to write the particular article. Where we find an American of equal competence with a foreigner, we give him the preference, chiefly on the score of convenience. But whenever, as frequently happens, the scholar who is indisputably best qualified for that particular topic happens to be a foreigner, we assign the article to him. In order to afford them the fullest measure of opportunity we have asked our foreign contributors to write in their own language. Therefore articles by foreigners, with the rarest exceptions, have been translated by our staff, so that the contributor must be held responsible only for the content, not for the form.

In the making of the Encyclopaedia we have had three purposes in mind. In the first place it is intended to provide for the scholar a synopsis of the progress that has been made in the various fields of social science in the broadest sense of the term. The student of any particular science should not only find here factual and methodological information of value, but will also have his attention called, perhaps in a hitherto unusual way, to the relation of his own science to the other disciplines involved. What is probably more important at this time, when such rapid advance is being made in more or less untrodden paths, the Encyclopaedia may be expected to serve as an incentive to the votaries of the younger and more inchoate sciences in order to bring to fruition what is now only in germ.

Secondly, the Encyclopaedia will, it is hoped, appeal to a much more numerous class which for lack of a better term might be called the intelligentsia in the various countries. It ought to furnish an assemblage or repository of facts and principles which will subserve the interests of all those who are keeping abreast of recent investigation and accomplishment. It is for this reason that we have made every effort to keep the articles free from all scientific jargon.

Finally, amid the welter and confusion of modern thought, it has been our hope that the Encyclopaedia would constitute a center of authoritative knowledge for the creation of a sounder and more informed public opinion on the major questions which lie at the foundation of social progress and world development.

INTRODUCTION: PART ONE

The Development of Social Thought and Institutions

What Are the Social Sciences?

From the very beginning of analysis and classification the field of science has been divided between physical nature and the phenomena of mind. The natural sciences have to deal with the phenomena of the universe in which our world forms so tiny a speck. By common consent, although not quite accurately, we contrast with these what are traditionally termed the mental or cultural sciences, those that deal with what takes place in man himself, in the realm of his mental life. We say "not quite accurately" because it is clearly inadmissible to assume that the mind is entirely independent of the body or that the mental processes are not in themselves subject, in part at least, to the play of natural forces.

Accepting, however, the common distinction between the natural sciences, on the one hand, and the mental or cultural sciences, on the other, it is obvious that the latter fall into two categories. The one deals with man as a separate individual, conceived of as dissociated from his fellow beings. The discipline of logic, for instance, deals with certain mental processes of the individual as a separate entity. Other sciences treat of man as a member of a group. In contrast to the separate wants, which can be satisfied by the unaided action of the individual, are wants experienced by the individual which can be satisfied only by associated or group action. These we call the common wants. Common, like separate, wants are experienced by the individual; the difference consists in the appropriate methods of satisfaction. In the one case the satisfaction of the want is obtained by unaided action; in the other by associated action. The phenomena thus related to group activities are commonly called social phenomena, and the sciences which classify and interpret such activities are the social sciences. The social sciences may thus be defined as those mental or cultural sciences which deal with the activities of the individual as a member of a group.

Since the common wants of mankind are exceedingly diversified, the group activities designed to satisfy these wants are correspondingly manifold. In the measure that these group

activities have been subjected to study, the social sciences have multiplied. They may be said to fall into three classes—the purely social sciences, the semi-social sciences and the sciences with social implications.

Perhaps the earliest of the social sciences is politics, for the most important of human groups has in general been the state. The state is indeed not the earliest group, nor has it always been the most important. In the millennia which have elapsed since the advent of man, the state was a relatively late comer in the succession of human associations. When scientific discussion arose in Greece, the pre-political groups had dwindled to insignificance or had been absorbed by the all-embracing state. The chief concern of the Greek sages was accordingly politics or political science because it dealt with the *polis*, the highest form of the self-governing commonwealth.

On a somewhat lower plane, in the purview of the Greeks, stood the second of the social sciences, economics. For while politics dealt with the state—the noblest embodiment of human striving—economics had reference to the *oikos*, the household which represented man's property relations. The right ordering of the household—including in one's possessions his wife, his children and his slaves—was indeed important; but the acquisition of wealth, especially in what we should nowadays call business, seemed to the Greeks to stand on a distinctly lower level.

When in the sixteenth century the problem of the acquisition of wealth shifted from that of individual salvation, as typified by the mediaeval usury doctrine, to national strength and power, the way was prepared for the advent of modern economics. Because of these national prepossessions, de Wetteville suggested the term political economy; for it was the national state which was to shape the new system of wealth relations. So strong was this feeling that even Adam Smith, despite his doubts as to the desirability of government interference, could not escape from fastening the term political economy on the discipline which he did so much to develop.

It was over a century later before the real social implications of the science were perceived, with a consequence that its leading votaries reverted to the old name given to it by the Greeks and that today we speak of economics, or sometimes of social economics. The political implications are indeed apprehended, but even more than politics itself economics is nowadays recognized as primarily a social science.

The third of the older disciplines that we trace back to the Greeks is history. From the outset history has laid claim to a field co-extensive with human interests. In the work of Herodotus history appears more closely related to the art of literature than to any science, and throughout the centuries history has maintained the union of art with science. In the hands of Thucydides history centered its interest in the state. Its spirit became essentially scientific, and its methods and results represent important contributions to political science. Among the classical and mediaeval successors of Herodotus and Thucydides, while many were essentially annalists or litterateurs seeking dramatic or epic material in past events, the function of history as an inquiry into the genesis and development of political forms and institutions was never entirely forgotten. History has never actually been "past politics" alone; but until comparatively recent times it has served the social sciences mainly through the material it afforded for the interpretation of politics. In the last century history has not only become far more rigorous in its scientific method, but it has extended its scope to the inclusion of the manifold phenomena of human life, individual and mass phenomena as well as those of formal political organization. Thus history has become an indispensable source of material for the interpretation of all manner of social processes.

The fourth of the older social disciplines is jurisprudence. Even in primitive society certain customs hardened into the rigid coercive relations that we call law. But it was long after the legal systems of relatively advanced states had developed, that law was recognized as an embodiment of justice and that jurisprudence arose. It was primarily the Romans who were led to cultivate this science because of the need of solidifying their world empire. The civil law, like the common law, yielded the chief opportunities that existed in the Middle Ages for the discussion of what were the most important relations of man to man. Next to

theology law was the moving force in the creation of the mediaeval universities. It was the most significant of the cultural sciences, and its votaries far outnumbered those devoted to politics or history.

Although Rome sought through its *jus gentium* and *jus naturale*, as England later did through its system of equity, to loosen the rigidity of the early system, the accommodation of the old legal forms to the newer social habits was slow. To this extent jurisprudence was conceived as something quite independent of, and unrelated to, the other social disciplines. It is only in very recent times that a change for the better has ensued. More and more have we come to recognize the reciprocal relations of law and economics; more and more has criminal law been influenced by penology; more and more do we hear of the new sociological jurisprudence. What is taking place, in other words, is a recognition of the fact that legal relations are inextricably intertwined with the other phases of human association, and that an adequate legal system must always reflect the myriad forms of social life. Modern jurisprudence, abandoning its early claim to complete independence, has been definitely recognized as one of the social sciences.

Thus the four older disciplines—politics, economics, history and jurisprudence—have outgrown their early separatism and have increasingly realized their interpenetration. Each is gradually recognizing that it is primarily a social science and that this reciprocity enriches its own domain and deepens its own conclusions.

While the disciplines thus far considered reach back to the beginnings of scientific endeavor, there are others of more recent origin, a result of the modern curiosity as to social relations. The characteristic feature of these newer disciplines is that they arose at a time when a growing recognition of the intertwining of all the human strands in the texture of life was leading to a disappearance of separatism in the older sciences. The newer sciences have thus never presented so hard a crust of tradition to be penetrated.

The first of the newer social sciences is anthropology. A study of early man, historic and prehistoric, became possible only after the rise of some of the natural sciences like geology. The unearthing of primitive artifacts—tools, implements and ornaments—led to the discussion of their uses or social connotations; and the later progress in the study of still existing

primitive groups broadened the comprehension of all manner of early customs. Thus anthropology was ready, almost from the outset, to recognize its affiliations with the other social sciences; and while it succeeded in throwing light on early political, economic and legal conditions it received in turn from these sciences many a valuable suggestion.

The second of the newer social sciences is penology. Until the time of Beccaria and Bentham there was no development of such a science because the offender was from the earliest times deemed to be the rightful object of communal vengeance. The commission of a crime was *lèse majesté*—an infraction of the king's peace or of the community's tranquillity. It was only natural for society to revenge itself on the malefactor by putting him out of the way. Criminal law was as barbaric as the conception of vengeance. But when it was recognized that attention must be paid not only to the rights of the group but to the possibilities of the individual, the first step was taken toward a more rational theory of punishment, and the science of penology was ushered in. A much longer step in advance, however, was taken when crime was recognized as at least in part a disease. The final advance was the realization of a large degree of social responsibility for both crime and disease. Modern penology is coming into intimate relations with economic and social conditions in general. Penology as a social pathology is contributing in full measure to the understanding of a normal social life.

Sociology, the next of the newer sciences, is only three-quarters of a century old, and has scarcely come of age even today. It is the most ambitious of all the social sciences, because in a sense the most comprehensive. As its very name signifies, it is an endeavor to lay bare the foundations of all living together, to elucidate the laws which lie at the basis of social intercourse. Far deeper than the economic or the legal or the political relations are those which govern human association in general. Sociology is the social science *par excellence*. It is also the most difficult of the cultural sciences. If it is not easy correctly to appraise one's self, how much more arduous is it to know one's neighbor or to evaluate one's own reactions to him. It is no wonder that sociology is still far from the definiteness and unity that characterize the older social sciences. Nor is it surprising that broad generalizations lacking adequate verification still hold an important place in sociological

theory. Nevertheless sociology remains the most important of human sciences. Only when real progress has been made in the elucidation of its laws, can we hope to attain a comprehension of life itself with its countless facets.

In the formative period in the history of sociology a wide range of social activities were for convenience subsumed under its rubrics, although not essentially related to its theories. Such, for instance, were the history and technique of charities and corrections, and the whole institutional structure built up to deal with them. What characterizes this entire field is the association of scientific inquiry with social action. The typical procedure is an investigation of a concrete situation as, for example, excessive infant mortality in a given area, followed by recommendations for remedial action, and the actual organization and administration of remedial measures.

For this whole range of activities the term social work has come into vogue, a term intended to emphasize the union of inquiry and action. Social work thus conceived holds a position analogous to that of engineering in its modern phases. Like the engineer the social worker starts with a concrete problem, and in his inquiries draws freely upon all the social sciences. So, too, in devising remedial measures he draws upon materials derived not only from the other social sciences but from the natural sciences and the arts as well. As in the engineering field, so in social work recent tendencies point to a vast extension in the future, with multiform specialization. Schools, hospitals, nurseries, housing, employment in factories or in commercial establishments, institutions for the handicapped may serve as examples of the fields in which the social worker is applying his professionalized methods of investigation and offering his professional services.

The sciences that have thus far been mentioned are the purely social sciences. Side by side with them we must put the semi-social sciences. These fall again into two categories. Some, however diverse their present-day importance, are social in origin and still retain in part a social content; others, although independent in origin, have acquired in part a social content. Starting in different ways, both groups have reached an identical position.

In the first group the most important is ethics, in a certain sense the most sublime of all sciences. For the right ordering of the moral life is the ultimate aim of human endeavor.

Ethical conduct is primarily a question of the individual, for conscience, the great regulator of conduct, is a personal matter. However, individual morality itself has been increasingly recognized as the resultant of social forces. Without the group there would have been no conception of right or wrong. The origin of morality is to be sought in the efforts of the individual to satisfy certain wants where unaided action no longer sufficed—as in the primitive elephant hunt or search for whales. As against the separate want which can be satisfied by his own action the individual experiences a common want which can be satisfied only through uniting with others. In order to accomplish the end the individual must now defer to his associates. He must cease doing certain things and must begin to do other things. Thus morality is born.

With the multiplication of the common wants new concessions to the other members of the group are continually made, until there emerge certain standards of conduct which are calculated to achieve the desired results. The concepts of right and wrong are thus social in their origin, although it is largely an unconscious process by which the criterion of the distinction is relegated to the individual himself. His conscience develops and the feeling of moral obligation becomes an essentially personal matter from the sway of which the finely attuned individual cannot free himself. The categorical imperative is the last word of individual conduct.

While the science of ethics thus deals chiefly with the problems of the individual, the increasing contact between groups of all kinds has engendered a new aspect of the moral problem, that of the conduct of groups toward each other. It is precisely in this sphere of activity, international and intranational, that the least progress has been made. Group morality is still far inferior to individual morality.

Ethics, therefore, despite the fact that it deals primarily with the individual conscience, is a social science in part, not only because social phenomena are continually creating individual reactions, but also because the contacts of social groups are responsible for the constant emergence of new moral problems. Social ethics constitutes today a not insignificant part of the moral sciences.

Analogous to ethics is education. It is perhaps true that education is not a product of the group in the same sense that individual morality

is the outcome of social forces. Nevertheless education is also, to some extent at least, social in origin. While pedagogics deals with the unfolding of the individual mind and the strengthening of the individual aptitude, it has always been recognized that isolation is incompetent to achieve the desired results. The activity of the individual in the group and the reactions of the group on the individual are of signal importance. Not in vain have schools and classes been invented; not lightly to be dismissed are the educational functions of play, of song and of dance, all of which connote a social origin. Moreover we must not forget that education for the satisfactory accomplishment of the social duties is an indispensable part of all modern curricula. Finally education, in the wider sense, has nowadays come to be predicated of the group as well as of the individual, even though the technique of group education must naturally differ. Education is thus partly social in content, partly social in aim, partly social in method, and may therefore be deemed a semi-social science.

In contrast to ethics and education are those sciences which, originally separate, have acquired a social content. Philosophy, in a certain sense the forerunner of science, was long considered as something entirely independent. When we deal with the final interpretation of life, of thought and of conduct, which we call philosophy, we seem to be treading on ground unbroken by science. But in proportion as parts of the unknown are converted into the known, new sciences are detached from the all-embracing philosophy and pursue a life of their own. It was in this way that chemistry and physics arose out of the mediaeval natural philosophy, and that politics and economics were separated from moral philosophy.

The social relations of man not only constitute one of the many domains still cultivated by philosophy, but they have also acquired a new significance as a recognized factor in the formulation of philosophic doctrines. For it has become increasingly clear that not a few systems of philosophy have themselves been, if not dependent upon, at least modified by, the social and political environment. The character of the problems and the methods of solution have been, in part at least, influenced by social conditions. The consequence is that not only does social philosophy as such demand growing attention but that all philosophy lends a more willing ear to social discussion. In this sense

we may speak of philosophy as in part a social science.

In psychology the transition is more unmistakable. It affords, moreover, an admirable illustration of the way in which the metaphysical elements in philosophy give way to scientific elements. The study of the mental processes of the individual was a favorite field of philosophy and split off into an acknowledged science only when, with the aid of the newly born biology, laboratory methods were applied to the phenomena of individual sense impressions, reactions and the like. Scarcely, however, had psychology vindicated its claim to be a separate discipline than as a study of human behavior it was recognized to be in part social in character. With an ever deeper knowledge of the mechanistic and the biological foundations of life and thought, the psychologist has come to recognize that the entire process has been molded by the human as well as the natural environment, and that the concept of the isolated individual is untenable as an explanation of actual fact. Psychology is therefore becoming social in a double sense. We must interpret the individual mechanism of mental processes, in part at least, in terms of a social environment; and secondly we have to deal with the thought process of the group as such, that is, of the individual not simply as unconsciously influenced by others but as purposively cooperating with others.

In contrast to the purely social sciences as well as to the semi-social sciences, there remains the last category of sciences, some of them natural, others cultural, which have well defined and increasingly recognized social implications.

Of these the first is biology. Biology as the science of life in its genesis and evolution has indeed a far broader scope than man. But in so far as it is applied to human beings it is compelled in its dynamic aspects to deal in large measure with the conditions of associative action. Moreover some of its recent offshoots, like eugenics, have an overwhelmingly social content. Finally, although later in the field than social psychology, social biology in the sense of the science of group changes is not without its numerous acolytes.

Slightly different is geography. Geography began indeed as the study of the earth's surface, but it soon advanced to a consideration of the territorial distribution both of natural and of social phenomena. As such it is in an excellent position to analyze the interaction between man

and his social heritage, on the one hand, and the natural environment, on the other. Through this description and analysis it is of great importance to the social sciences, enabling them to explain the regional peculiarities of human societies and institutions.

While biology and geography started out with no thought of man, the second group of the sciences with social implications was virtually limited from the outset to man. Although the scope of medicine has been extended to animals, it is still today overwhelmingly a human science. While, however, it necessarily deals with the health of the individual, medicine also has traversed the same double phase as some of the other cultural sciences. More and more does the physician realize that disease is in part a product of social forces. Moreover the reciprocal influence of individual and group is being increasingly attested by the newer development of social hygiene and public health. On all sides we are today confronted by the social implications of medicine.

Linguistics, in its social scientific aspects, has had a somewhat checkered career. With the development of comparative philology in the late eighteenth and early nineteenth centuries, it was widely assumed that language afforded an adequate clue to the dispersion and ultimate distribution of the races and the diffusion of institutions. Under late nineteenth century criticism the claims of the comparative philologists to authoritative interpretation of prehistoric movements of the peoples were much abated. Linguistics remains, however, an important instrument of social scientific inquiry. Judiciously employed, the history of words often sheds light on the history of institutions and modes of thought. The economist, the lawyer, the politician, the historian who neglects to arm himself with the panoply of linguistic science shows that he does not fully comprehend the possibilities of his own discipline.

Finally we come to the realm of art. It goes without saying that art as creative activity stands in contrast with science, whose objective is analysis and understanding. But artistic creation is dominated by values and these are, at least in part, of social origin. In the history of art there is much that helps to explain social institutions, and vice versa. No one who wishes to understand the operation of social laws in the modern world can afford to overlook the evidence offered by the arts.

EDWIN R. A. SELIGMAN

Greek Culture and Thought

I. EARLY GREEK CULTURE. The institutions of the ancient Greeks first appear, in a form tangible enough for historical consideration, in the Homeric poems. Although the picture of Greek society there presented is not a unified one, in general it may be called a tribal society in the process of evolution into more elaborate state forms. There were many tribes, each led by a king (*basileus*). The kingly office was hereditary and the kings claimed divine sanction for their rule. Nevertheless the Homeric kingship retained certain features of the more primitive type of tribal chieftainship with which the Greeks had entered the peninsula. The *basileus* was leader of the warriors of the tribe in their forays or larger military enterprises. In the field of war the military divisions were by brotherhoods and by tribes. The council of the king was still called "the council of the great-hearted elders"; but it is apparent that the more primitive stage of tribal organization, in which the council was actually composed of old men, was past. Its membership included chiefly active younger men who represented a nobility of landed gentry among the tribal warriors. In some parts of Greece the more primitive organization, in which the advisory council of the *basileus* was composed of actual elders of the tribe, persisted far into a period when most of the Greek states had long passed beyond the tribal stage. This was notably the case in Sparta, where the institution of the gerousia (composed of *gerontes*, old men over sixty years of age holding office until death) continued even into the Hellenistic period. Aristotle in his *Politics* criticized this Spartan institution from the standpoint of its life-tenure principle because of the danger arising from "intellectual old age." The duties of the council in Homeric society were still essentially primitive tribal. In war time its members formed an advisory board of strategy to the king. In times of peace it assisted him in composing disputes between tribe members. Throughout the *Iliad* and the *Odyssey* the power of the tribal kings was strictly limited by the necessity of putting all important questions before the assembly (*agora*) of the tribal

warriors for its approval before taking action.

In three respects the original tribal ideas of the early Greeks determined the evolution of Greek political institutions throughout the period of the preeminence of the Greek city-states in the political life of the Mediterranean world. These are: (1) the idea of citizenship as a privilege inherent in the descendants of the tribe members by right of birth; (2) the nomenclature of the divisions of the citizen body into tribes (*phylai*); (3) the persistence of the conception that ultimate sovereignty reposed in the citizen, or tribal, members of the state, who delegated executive authority to selected members of their number at the meetings of the assembly.

In the Homeric epics there is a distinct artistic effort to hold fast, as far as possible, to obsolete and archaic conditions of life which were fast disappearing when the poems were attaining their final form. Despite this archaizing tendency the life as there represented was, in the main, that lived by the Greeks in the period stretching from 1000 to 800 B.C. Villages and towns were appearing everywhere. Economically the Greeks of the Homeric period carried on exchange of goods by barter. Trades had already become specialized, without any noticeable specialization of craftsmanship within a given trade. Distribution of the products of the skill of carpenter or metal worker was strictly local. Prior to the Homeric period, at the time when the Greek tribes were slowly moving downward into the Greek peninsula and fusing with the pre-Greek population, the countryside of central and southern Greece was dominated by strongholds, heavily fortified with stone and placed upon hills. These were the "Mycenaean" palaces, so well known from the excavations at Mycenae and Tiryns in the Peloponnesus. They had afforded the subject population a refuge from attack by wandering tribes on land or by pirates from the sea. As the Greeks took over the rule of the country, these fortified palaces became in some instances the centers of their tribal rule and the seats of their local governments. Where the Mycenaean

strongholds were destroyed in the struggle with the invading Greeks they nevertheless suggested to the new people the form of the simpler fortified refuges which they, in turn, established.

During the course of the two centuries (*circa* 1200-1000 B.C.) which precede the Homeric period, occurred the eastward and south-eastward expansion of the Greeks which ended in the occupation of the islands of the Aegean Sea and the western coast of Asia Minor. In this expansion into areas occupied by alien peoples the early bands of Greeks were of necessity compelled to establish themselves in the walled towns which already existed there or to construct the fortified refuges with which they had already become familiar on the mainland of Greece. These are the impulses which determined the physical setting for that important political institution, the city-state (*polis*), which characterized Greek political life and determined in considerable degree the cultural development of Greece throughout the classical period of its expression.

In its use by the ancient Greeks the word *polis* developed two distinct and separate meanings. It was the physical city, a group of private dwellings and public buildings concentrated in a given area; but in its meaning of "city-state" it was a political concept, a state form containing several essential ideas. The *polis* as a state might cover a considerable area; but the center of this state and the seat of its rule lay in the physical city with its enclosing walls. It must be a "free" state externally, in the sense that it had the right to live in accordance with laws of its own making. The characteristic feature of the Greek landscape is its valleys lying like bowls, the sides of which are mountains. The opposite slopes of these mountains again form the inner rim of similar bowls on the other side. It was this peculiar geographic conformation of the Greek peninsula which determined the fact that the area of the Greek city-states was usually so restricted. Within such an area, sharply delimited by nature, the towns and villages tended to unite to form one state. This actually occurred in Attica where the three divided plains which constitute geographic Attica early united to form the city-state of Athens. It occurred similarly in Laconia where the city of Sparta united a large territorial area into a single city-state. In other plains just as sharply delimited by nature, as in Boeotia, unity of the entire area into a single *polis* could never be maintained for long because of the tendency

of each town to assert its right to a free and autonomous life. In the western parts of Greece, such as Aetolia and Acarnania, there was no urban development until very late in Greek history. In these and other backward parts of Greece village life and primitive tribal organizations persisted. Throughout the history of Greece, therefore, we find side by side tribal states with village grouping and tribal states with a civic center, i.e. city-states. The desire for complete autonomy was equally characteristic of the two types.

There are no data regarding many important problems of the early history of those Greek-speaking tribes which came from the north into the Balkan peninsula and by assimilation with the native population formed the Hellenic people of ancient times. Information concerning the intermarriage of the Greek-speaking tribes with the natives is irretrievably lost, and with it all knowledge of its social results. It is clear from the Homeric poems that the economic basis of the resultant Greek life was primarily agricultural; but the Homeric Greeks were already sailing the seas. What the new conditions were which impelled them into navigation we can only guess. The fact of a colonial expansion from the Greek peninsula, extending from about 800 B.C. to 600 B.C. in its intensive period, is known from Greek tradition and from the results of that movement. In the space of these two hundred years the Greeks had rimmed with agricultural communities and trading towns the Black Sea, the Thracian coast, much of the coastal area of Italy, Sicily and southern Gaul, the eastern littoral of Spain, with occasional outlying posts on its south coast. They had established a Greek trading community at Naucratis, on one of the mouths of the Nile. At Cyrene in Libya they had a strongly entrenched colony. The causes of this colonizing activity must have been many. In the Greek peninsula the earliest colonies were presumably due to relative over-population in a land which was four-fifths mountainous and therefore restricted in its possibilities of food production. In the cities of the Asia Minor coast, industry had developed early. There the need for raw products, as well as markets, determined that the colonies sent out, notably by the city of Miletus, should be from the outset trading posts rather than agricultural communities. With the development of industries in the homeland of Greece itself, the requirements of a growing industrial production and commerce soon be-

came the dominating factor. In this connection the problem of relative importance—whether colonization determined the swing to industrial life in the home cities or the growing industrial trend at home motivated and caused colonization—is not possible of solution. The interaction of the two movements may be assumed as certain.

The results of this widespread colonizing activity were vital and constant in the material and intellectual development of the Hellenes. It gave invigorating contacts with new worlds and differing cultures to a people singularly receptive of new ideas and peculiarly gifted with ability to transmute these into modes of their own expression. It brought the Greeks a diversity of experience of men, of countries and of customs which must have affected them deeply; and it came at a fortunate time, when their own customs had not yet crystallized into set forms. There is no possibility of answering the question whether the exploits of these unknown adventurers of the sea were an expression of an intellectual restlessness and curiosity of mind already developed, or whether colonization is to be regarded as a factor in developing that exploring habit of mind which characterized Greek intellectual life for the succeeding four centuries. Greeks of the distant colonies were compelled to expend their energies in the necessary activities of a pioneering and commercial life, such as the building of cities and development of trade. Their cultural energy, as seen in the ancient temples at Selinus in Sicily, displays them as true Greeks in their architectural expression and in similar utilitarian applications of the native Greek sense of form. No outstanding names of colonists appear, however, in sculpture, painting or literature until about 500 B.C. Because of the practical requirements of colonial life and the greater cultural maturity of the eastern Mediterranean, the cities of the Aegean littoral were the first to draw the artistic and intellectual profit of the colonizing activity. After 500 B.C. and in the eastward expansion of Greek culture after Alexander, both western and eastern Hellenism of the *diaspora* came into its own in power of Greek expression.

Though the colonies of the period 800–600 were sent out by single cities, the relation of colony to mother city was distinctly not that of a dependent, or even of an inferior to a political superior. From the mother city the colonists took the sacred fire from the altar of the city god. They adopted from her their religious

cults and their festivals. As a rule they established a similar political organization, using the same tribal names. Often they used the same code of laws. But the colonists lost their citizenship in the mother city which they had left and became citizens of a new city-state. They took with them as the fundamental gift of their home environment the idea of the complete independence of their new home in its statehood. The colony did, however, acknowledge a filial relationship which might well determine its orientation on the side of the mother city in case of war. It granted to the mother city an indefinite religious primacy; but insistence upon actual political leadership was rarely sought or granted.

In many aspects of their civilization the Greeks formed a single people, unified by common religious beliefs and practises, and by the use of dialects of the same language which all could understand. They were all conscious of a cultural Greek unity as against all non-Greeks. These they classified under the one comprehensive term of *barbaroi*. Despite this feeling of unity they remained a people divided into hundreds of little independent states. Complete political disassociation was the normal condition among them and the ideal desired by each. Under the stress of external dangers which affected all these separate units alike and which seemed paramount to their constant local animosities, they could unite for temporary action. The danger once removed, the separative force of the tribal state ideal always disrupted the union thus attained. Several other forces within the Greek world tended to force the centrifugal city-states into larger or smaller unified groups. One of these was imperialism, under which the more powerful of the Greek states were constantly attempting to establish themselves in a dominant position (*hegemonia*) over less powerful neighbors. Economic or other social advantages also might motivate the subordination of city-state autonomy and the formation of larger and more comprehensive political forms. In the situation thus created lay a distinctive peculiarity of the political and social background of the Greeks in antiquity. A pan-Hellenic cultural unity existed, self-recognizing and acknowledged as well by the non-Greek world; but no single political organism of any permanence could develop out of the aggregate of city-states; and no Greek nation ever developed in antiquity.

Under this situation of city-state particu-

larism developed the variegated forms of cultural activity which have made the ancient Greeks stand out as so interesting a people. It is generally conceded that their amazing intellectual activity was in great degree conditioned by the intensity of the political life engendered in the autonomous city-state units. In that it rendered difficult any continuous political effort on the part of the Greek people as a whole, city-state disunion was also the source of the outstanding weakness of the ancient Greeks.

Neither in the political theory of the Greeks nor in their political practise did the constitution of the tribal state need to be of any one type. Throughout its history as an independent state Sparta, in its outward form, remained a kingship with two kings reigning side by side. Macedon assumed its position of leadership in the Greek world in the fourth century B.C. under a monarchic form of government. Under the absolute monarchy of Alexander and his successors Hellenic civilization was spread over western Asia and Egypt, the ruling dynasties being, for the most part, descendants of the old Macedonian nobility. But it is certainly true that the typical forms of Greek culture which have been admired by posterity were generated in the autonomous and democratic city-states.

In the Athenian state the lifelong tenure of military and executive leadership held by the tribal king had completely disappeared by 683 B.C. In its place appeared a collegiate body of magistrates, the nine archons, elected by vote of the tribal assembly for a one year term. The war archon (polemarch) was commander-in-chief of the military levies of the state. In the hands of one of the archons, distinguished as *the* archon, lay the executive authority in civil administration. Proof that this process of change in the Athenian state was one of evolution, rather than revolution, lies in the retention in the hands of the magistrate called the "king archon," of the religious leadership which had formerly been an attribute of the tribal king. The kingship had, presumably, not been abolished; but the king had been shorn of his important functions. In addition to these three archons six others made up the board. These were the lawmakers (*thesmothetes*) who combined the functions of judges and overseers of the laws of the state.

The disintegration and decentralization of the functions of the tribal kingship as it appears in the Athenian state were typical of a general movement common to many of the Greek states of the time, producing similar kinds of elective

magistracies. Although these varied widely in name and in the details of their functioning they show a basic similarity. Their typical features are: election by the citizen assembly, annual tenure, the collegiate form, and collegiate and individual responsibility.

Typical of the same period is the weakening of the tribal idea of government as manifested in family, clan and tribal action in the state, and the substitution in its place of corporate action of the entire citizen body. This movement may be designated as an evolution from primitive tribal ideas of government to comprehensive civic responsibility and action. Our knowledge of the codification of the customary civil and criminal law and procedure at Athens which is ascribed to Draco (*circa* 621 B.C.) is meager. It is sufficient, however, to show that the state had assumed in homicide cases the right of punishment which had formerly rested with members of the immediate family or of the brotherhood (phratry) of the victim. Certain rights in procedure and punishment were still left to the family and clan; and in criminal cases these social organisms continued to hold decisive rights of reconciliation and decision of penalty in minor particulars, even throughout the fourth century B.C. In Athens, and in other Greek states also, family and clan rights were still observed in the seventh century B.C., and were retained in obsolete form, but still as theoretical rights, into the time of Demosthenes. In this basic tribal right of family and clan groups in civil and criminal litigation lies the explanation of the strange fact that the Greek states, in the period of their development as autonomous political entities, did not provide for any public prosecuting agency representing the right of the state itself to initiate the processes of justice. This action continued to depend upon the unorganized initiative of individuals, whether of the family or clan, or any interested member of the entire group of citizens.

In the Athenian state of the seventh and sixth centuries political activity centered about the struggles of prominent clans for preeminence. A radical change in the structure of the state was made in 508 by Clisthenes, an Alcmeonid. In the place of the old system of voting under a division of the state into four primitive kin tribes, he substituted an artificial division into ten units still called tribes. Despite the retention of the name and concept of the tribe, this change denotes the passing of systematized voting on the basis of kinship and clan solidar-

ity. Membership in the ten new tribes was geographic, but under a distributive system in which three separate and non-contiguous territorial areas were combined in each so-called "tribe." In this process of redistricting the state for voting purposes, Clisthenes did not destroy the actual clans and phratries. They continued to exist, but only as religious and social organisms. Their retention was a concession, on the part of a leading political mind of that time, to the strength of the tribal feeling.

II. THE CITY-STATE DOMINATION. In the great congeries of Greek states in the fifth and fourth centuries hundreds of small polities existed, most of them with democratic governments. Where monarchies persisted, the powers of the monarch were limited by the electoral and legislative rights of the assembly of citizens. The tribal origin of Greek citizen privileges was everywhere maintained, under whatever form these states were organized. Citizenship was acquired by right of birth from citizen parents, sometimes on the paternal side alone, sometimes on both sides. Only by vote of the citizen body upon special cases could citizenship be extended to those who had not inherited it. In cases of great need the privilege might be voted to a group; but this practise was rare. As judged by the standards of the inclusive adult citizen privilege of modern democratic practise, the Greek city-states were actually organized as oligarchies. The correct approach to their understanding must, however, be from the viewpoint of the political practise of the pre-Greek cultural states of antiquity. By comparison with the absolute or the feudal monarchies of the ancient Near East the Greek experiment in government receives its sanction as political democracy and assumes its position of historical importance. The word *demokratia*, the rule of the *demos* (tribal citizen group), was coined by the Greeks; and they were the first people to establish any form of popular rule.

In their mode of operation these city-states were pure democracies, each citizen being compelled to come to a central place to cast his ballot in elections, to vote upon legislative matters of greater or lesser import or to determine questions of purely administrative routine, such as the sending of an embassy to another city-state. In the last case he must vote upon the number and membership of this embassy, upon the amount of its *per diem* expense account, and

empower one of the financial boards to make the required payments. The cumbersome and time-consuming character of the machinery of pure democracy was somewhat relieved by the fact that it operated on the committee system. The council (*boulē*) was in effect a committee of the assembly, elected annually out of the citizen body (i.e. the assembly itself), which put into completed form all matters for presentation to the assembly and arranged the agenda for its fixed and special meetings. In the more populous city-states where the *boulē* was large, a small offshoot of this body, customarily the councilors of one tribe, functioned as a subcommittee, preparing rough drafts for action by the full council. At Athens, as in many other states which copied the Athenian system, this subcommittee was called a *prytany*. When the assembly met to take final action, the council dissolved into the assembly of citizens, as under the usual committee system.

As a result of the lack of statistics for antiquity our knowledge of the relative numerical proportion which existed between the citizen bodies of the Greek polities and their total populations is a matter of approximations. For the Athenian state, which offers the best chance for a trustworthy estimate, a recent view of the composition of the population in 431 B.C. gives the following results: male citizen body over 18 years of age about 50,000; adult male metic population about 15,000. The total free population has been estimated at about 200,000. For the total slave population 80,000 to 100,000 has been taken as a conservative guess. On this basis the entire population of Attica would necessarily be put at about 300,000 persons.

The class of metics (co-residents) in the Athenian state corresponded to a similar group found in many other Greek states, although under different class names. They were men of families originally alien to the city which had admitted them to metic status. In case the family remained in the state the classification seems to have been hereditary, except in the rare cases of advancement of metics to citizen status. Metics enjoyed for themselves and their families all the protective rights held by citizens; but they could hold none of the state offices, neither could they vote or own real property in the state. They must each have as patron some citizen to stand as surety of their good behavior. They had to pay a direct metic tax of twelve drachmas for each man, six drachmas for each unmarried woman. In other respects they

were on a footing of equality with citizens, serving the city-state in its wars and taking part in all public religious festivals except those distinctly reserved for old tribal brotherhood and clan observance. No social grouping of metics is known. The conclusion is therefore warranted that they were completely assimilated into the state organization and were dominated, like the citizens, by the idea of devotion to the all-powerful *polis*. The metics at Athens, and probably in other Greek cities, were skilled laborers, small shopkeepers and street hucksters, or were engaged in transportation services. Building accounts of the construction of the Erechtheum for 409-408 B.C. give the following relation of contractors and workmen engaged: total 71, distributed as follows—slaves 16, metics 35, citizens 20. These figures may be taken as roughly typical of the general situation in the Greek urban commercial centers of that time, such as Chios, Samos, Corinth, Corcyra, Syracuse. States which had failed to move forward with the industrial spirit of the time (such as Sparta), and the non-urban, agricultural and more primitive states of western Greece, presented quite different conditions.

The acceptance of alien Greeks or of barbarians as protected subjects and the permission of continued residence granted to them were an outcome of the growth of industry and trade due, first, to the colonization movement, with its creation of distant markets demanding goods of Greek manufacture and supplying raw materials from central and northern Europe and, second, to the invention by the Lydians, in the seventh century B.C., of the use of coined money, first in electrum (natural mixture of gold and silver), then in gold and silver separately. This discovery was eagerly taken over by the Greeks. It spread rapidly in the sixth century in the handicraft industrial communities of the Aegean littoral and into the colonial markets, giving a new impulse to the industrial movement which had accompanied colonization by speeding up the processes of exchange. With the growth of the cities the complexities and exactions of administration increased. In the democratic movement of the fifth century the admission of all citizens, of whatever class, to all magistracies and administrative boards had been carried through. The time and the energies of the citizens were in some degree being consumed by the heavy task of ruling in their direct democracies, whether in electing magistrates or holding magistracies, or participating in legis-

lative meetings or in jury service. More consuming in time and energy was the citizen obligation of military service in the constant wars of the fifth century. These were the circumstances which explain the presence of so large a number of metics at Athens and in other industrial city-states, and the preponderance of combined metic and slave labor over citizen labor as exemplified in the Erechtheum building inscription. Other changes also followed upon the use of coinage. It changed the nature of wealth through the accretion in private hands of money surpluses. This in its turn hastened the passing of the collective economic system of the Greek tribal society and the political downfall of the tribal aristocracies whose wealth was based on land holding. In combination with colonization coinage tended to release latent individual energies and to transmute these into productive effort.

The same combination created an equally momentous change in the slavery system of the Greek world. In the agricultural-pastoral economy of the Homeric world field and household slaves appear, but they were relatively few in number. As the handicraft system spread in the Greek world, the Asia Minor cities first took over the industrial practise, long in operation in the Babylonian area, of using slaves in manufacturing. From the Asia Minor cities industrial slavery as an economic system spread into the Greek peninsula. With it and with the increasing wealth of individuals, household slavery progressed likewise; but this situation was prevalent only in the industrialized city-states. In the non-industrial communities where life was still largely agricultural, either free agricultural labor dominated or, as in Thessaly and Sparta, a helot system left no room for slaves.

Industrial slavery in the Greek world cannot be dismissed as a system bad in its total social and economic effects. From the humanitarian standpoint it seems not to have been so bad as the helot system, which in Sparta produced a tension between the master and serf classes resulting in a constant state of hatred and fear. One form of slave employment, that in mining and stone quarrying, was distinctly bad. Its evils lay in too long hours of work under trying working conditions. In individual cases the evils of mining slavery might have been deprecated, though the writer of the tract *On the Athenian Constitution* makes no mention of its bad features in his discussion of a reorganization of the Laurian mines and their use of

slaves. In Athens in the fifth century public opinion, if it had seriously deplored the evils of slavery in the mines, might have found expression through the medium of comedy or tragedy. The lack of such protest bespeaks the general callousness toward suffering characteristic of Greek and Roman antiquity. This callousness expressed itself in the legal provision which permitted the taking of testimony from slaves by torture.

The outlook for programs of social betterment through legislation was therefore limited within each Greek city-state. One organization in the Greek world is known to have constructed definite rules for amelioration of the savagery of war between the Greek states which were included in its membership. This was the Delphic Amphictyony. The amphictyonies were very old organizations of neighboring cities centering in some outstanding temple, and had originally been established for the better celebration of a particular worship through unified action. There were a half dozen of these in the Greek world. The functions of the representatives of the member states in the amphictyonies, who met at stated intervals in council, were to look after the protection and administration of the sacred land and other properties of the god, and to provide for the conduct of the sacred games. The representatives of the member states of the Delphic Amphictyony were required to take oath that they would not destroy any city of the amphictyony or cut it off from running water, either in war or in peace; and that, if any community adhering to the amphictyony transgressed the agreement, they would make war against that member and destroy its cities. The negative implication must be drawn from it that such practises were permissible in wars with all non-Greek peoples and with all Greek states not members of the amphictyony.

In other ways, also, the later forms of interstate relations between the different Greek communities betray their tribal origin. In primitive tribal thought the "outsider" is considered an enemy; and the Greek word for enemy actually means "outsider." But the stranger who appeared within the tribal territory and asked safe conduct and protection, with appeal to the gods, had to be accepted as a guest and friend (*xenos*). He was under the protection of the god and of the family which might have received him. When he returned to his own home a reciprocal and hereditary re-

lation of "guest-friendship" had been established between his family and that of his protector in the foreign state. This is the situation which existed in the time of the Homeric poems. With the great increase in intercourse and movement of traders which colonization brought, the custom of "guest-friendship" between the subjects of different states became a regulated and recognized feature of Greek life. Just as in the case of the metic, the stranger temporarily domiciled in another state for trading purposes was required to have the protection of a citizen. When such guest-friendship had not been established between the family of the stranger and some citizen in the foreign state, the stranger had no legal status. To meet this situation there arose the *proxenia*, a system in which some one citizen stood "in place of guest-friend" (*pro-xenos*) to all visiting aliens from some one city-state. So Alcibiades was guest-friend to all Spartans who might come to Athens. In the fifth and fourth pre-Christian centuries the proxeny system gave way before the custom of establishing definite commercial treaties and treaties of friendship between city-states, with recognized mutual rights of freedom of visit and intercourse for the members of the two states; and in the many proxeny inscriptions which have come down to us after that time "guest-friendship" has become a mere honorary title bestowed by the city-states upon aliens who had in some way been of service to them.

In Greek social life the ideas of the maintenance and solidarity of the family, which is the basal unit in clan, tribe and state, play an important part. Aristotle in his analysis of the *polis* as physical city recognizes the ascending series of house, village, city. On the political side his series is family, tribe, state. As far back as historical research can trace the Greeks they were monogamous, and complete control of the family and household lay in the hands of the eldest of the family group. In view of the tribal basis of citizenship it lay in the interest of the Greek state to preserve each citizen family, so that the number of citizen families both for religious and for political reasons might be maintained. Out of this fact arose a peculiar provision regarding female inheritance. The inheriting daughter of a deceased family head who had left no living sons might be claimed in marriage by the next of kin. Upon the girl it was a legal obligation to marry a man of her father's blood as near to her as possible. The

paternal uncles of the girl and their sons, in a definite series, were obligated to undertake the marriage of the heiress. According to the laws of Gortyn in Crete of the sixth century B.C., greater right of selection was left to the woman. If she agreed to renounce one half of the inherited property to her male next of kin, she might herself make choice of her husband, but within the circle of the clan of which her family was a part. In the greater legal freedom of women which is to be noted in this Cretan law, there may be preserved a characteristic of the culture of the pre-Greek, or "substratum," people of Crete. The wall paintings of the Minoan palaces of Crete certainly portray a life in which the social conventions applying to women were less constraining than those prevailing in the Greek cities of the fifth and fourth centuries B.C.

A complete household, according to Aristotle, consisted of the father, wife, children and slaves. The father of the family was lord of the household. He was guardian and representative of all the family members before the state and before the gods. The oversight of the household cult lay in his hands; and he was the legal representative of wife, slaves and minor children. He had the power to determine whether a newborn child should be exposed, that is, whether it should be left either to die or to be picked up by a passer-by and raised as a slave, unless proof of free birth could be brought forward. Exposure was more frequent in the case of female infants than in that of male, both for economic reasons and for purposes of family continuation. The complete sway of the family head over his household which characterized early Greek relations was somewhat curtailed in the period from 800 to 500 B.C. as a result of the growing power which the state assumed as against the family and the clan. Such curtailment is seen in the legislation of Solon in 594 B.C. to the effect that when a male child had once been formally presented to the state by the citizen father, the father thereafter lost to the state the right of life and death. There remained to him still, however, the right to assign a minor child for adoption into another family. Moreover he had the power, in case of grave disobedience, to thrust a son out of the family organization, but only by public announcement through a herald.

The position of women in Greek society of the sixth, fifth and fourth centuries was on the whole an inferior one, both legally and socially. The explanation of this fact is to be found in

the original tribal structure of the Greek state, which resulted in a heavy emphasis upon the continuation of the family and tended to make marriage an institution destined to that end, and women the necessary instruments for the maintenance of the family life and its economic fortune. Greek women had no independent status in court. Married women were represented in court by their husbands. A divorced wife or a widow who left the house of her dead husband returned immediately under the protection of the head of her own house. In case a widow remained in her husband's house she became subject to the legal representation of her eldest son, who upon his majority assumed control of his mother's property. Divorce, like marriage, took place without the need of any official intervention. The husband could bring it about by the simple process of sending his wife away; the wife could leave her husband at will, although at Athens she was legally required to announce the fact before the archon. In Sparta childlessness of a wife was sufficient ground for divorce. There were, however, many ameliorating circumstances. The dowry which a wife brought with her in marriage was protected for herself, though customarily the usufruct of it went to the husband. In case of divorce, under ordinary circumstances, it was returned to her. In the sixth century laws of Gortyn the divorced woman received, in addition, a half of what her dowry had earned. Within the household the position of the legal wife could be both honorable and important. Among the poorer citizen classes the position of women was much less subject to restricting conventions than among the well-to-do. As free economic agents the wives of the poor appear in the markets selling vegetables or engaging in similar work. Even with respect to the upper classes it must be said that the grave monuments of the classic period and the tone of the Athenian drama of the fifth century speak strongly for the assumption that the actual position held by Greek women was considerably higher than the legal recognition of them would imply.

It is not possible to formulate any general characterizations of the economic life of the Greek world for the entire period from 700 B.C. to the conquest of western Asia by Alexander. The changes which took place in this long period were great, the local diversities which appear at any given time quite marked.

Certain features, however, seem fairly definite. The trade of the Greek world after the

seventh century encompassed the entire Mediterranean littoral. It was largely sea-borne trade. Transportation of goods and travel of persons by land were much more costly than by sea. Indeed it is one of the marked and constant features of the Greek and Roman civilizations that they remained thalassic, rimming the Mediterranean Sea, and that they tended to confine their expansion, both military and cultural, to its shores and hinterlands. The two persons who departed from this tendency were Alexander the Macedonian, in his conquest of western Asia, and the Roman politician Julius Caesar, in his conquest of Gaul and in his foreshadowing of the Roman expansion into Britain. It was for this reason, and by virtue of the consequences of their break from the traditional intra-Mediterranean viewpoint, that these two lives must be regarded as pivotal points in the political and economic history of antiquity.

In the sixth century the Ionian coast of Asia Minor was the chief center of handicraft industry in the Greek world. In the fifth century the center of gravity of manufacturing and of trade had shifted to certain cities of the Greek mainland. Two causes stand out as important in this movement. The first was the long continued war of the Greek cities with the Persian Empire, which was almost constant during the years 500-448 B.C. and brought about a considerable lessening of the trade with the East by way of the Ionian cities. The second was the great expansion of the Greek markets in the western Mediterranean in the sixth century. Among the mainland cities which reaped the benefit of their central position in the Mediterranean and Black Sea areas of Greek commerce were Corinth, Aegina, Megara and, above all, Athens. Inter-Greek politics and wars of the fifth century are marked by an increased emphasis, which was thoroughly conscious of its methods and aims, upon economic relations both in war and in peace. Particularly Athens, under the leadership of Pericles, maintained its sea power partly in the interests of the commanding economic position given to it by its hegemony over the Delian League. In the fifth century Athenian ships carried the bulk of the trade in the Aegean and Black Seas. After the Persian expedition of Xerxes in 480-479 B.C. Athens made a strong bid for the trade of the West. This brought the Athenian state as a strong competitor into the sphere of trade formerly controlled by Corinth. The clash of their economic interests is one of the tangible and

immediate elements in the growing feeling of hostility to Athens which brought about the Peloponnesian War. In respect to the Athenians a pamphlet of the period makes this statement: "They alone can have the riches of the entire Hellenic and non-Greek world. For if any state is rich in woods for ship building, where may it dispose of these, unless it persuades the ruler of the sea? If any state is rich in iron or copper or flax, where may it dispose of these unless it persuades the ruler of the sea? Indeed for these very reasons our ships are built." As compared with the fifth century, the fourth century was marked by a decrease of the trade of the urban centers of Greece itself in the western markets, caused by the development of local handicraft centers, especially in Italy. This constriction of the western trade sphere must be regarded as one of the contributing pressures which resulted in the invasion and conquest of the East by Alexander.

The variety of the articles of trade which came into the harbor of Athens, and some indication of the districts from which they came, are obtained from a comedy produced in the early years of the Peloponnesian War: "From Cyrene the ships bring us silphium stalks and cowhides, from the Hellespont tunny and all kinds of pickled fish, from Italy groats and ribs of beef. . . . Syracuse delivers pigs and cheese. . . . Egypt contributes sails and papyrus rolls; Syria, incense; lovely Crete, cyprus wood for the gods. In Libya ivory is to be bought. From Rhodes come raisins and dried figs that cause sweet dreams, from Euboea pears and apples, slaves from Phrygia, mercenaries from Arcadia, no-good servants and branded rascals from Pagasae [a Thessalian harbor], chestnuts and almonds from Paphlagonia. . . . Phoenicia furnishes dates and fine flour, Carthage, carpets and colored cushions." From this and many supporting sources it is clear that the industrial urban communities, of which Athens is the outstanding example, lived upon foodstuffs imported chiefly by sea. These cities exported in return the wares of their weaving, ceramics and other industries, whether produced in the homes of the craftsmen or in small hand factories. The largest manufacturing industry known to us was that of a shield maker in Athens which busied 120 workmen. This was exceptional. There must have been many small industries in Athens and the Piraeus which employed from ten to thirty workers. There was distinct specialization in industry, each shop

turning out objects of a single type such as shields, helmets, shoes, chitons or the like. Specialization of function within the craft occurs, as between potter and painter in ceramics, and cutter and sewer in sandal making. Training in craftsmanship was by the age-old apprentice system. This applies equally to training for medical practise, which was classed as a craft (*technē*), as were also sculpture and painting. A separate designation for the "professions" did not exist.

The area of Greece itself which can be successfully cultivated is about one fifth of the whole peninsula. Its soil, as compared with that of Sicily or that of the fertile valleys of western Asia Minor, is poor. With the colonization movement, as the handicraft industries grew in the Asia Minor cities and in those of Greece proper, grain was imported, constantly in greater amounts, from lower Russia, Egypt and Sicily. Small farming of grains still maintained itself in Greece, rotation of crops being by the two-year system of alternate planting and fallow; but grain production in peninsular Greece could not well stand against the competition of the more fertile terrains accessible to colonial shipping. A change to olive culture and the manufacture of olive oil for the colonial trade, as in Attica, and wine production, as in some of the Aegean Islands and on the coast of Asia Minor, brought a welcome relief in the fifth century to agricultural life in the older city-states centering about the Aegean. At the beginning of the fourth century a more scientific handling of the soil (advocated in books upon the subject), a better knowledge of the use of manures, a change by the more intelligent farmers to the three-field system of cropping, gave a renewed but temporary impetus to agriculture, even on the mainland of Greece. For the most part, however, the picture of Hellenic economic life from 600 to 300 B.C. shows a constant increase of industrial production, a gradual decrease in the importance of agriculture, a growing dependence upon grain raised by non-Greeks and increased difficulty in feeding the growing city communities. However much the political theorists might advocate the self-sufficient city-state as an ideal, its day in the progressive parts of the Greek world had passed.

Greek culture assumed its characteristic aspects in the fifth and fourth centuries. Whatever local differences may be established for the various Greek tribal groups and for the many

city-states, two elements characterized the religious attitude of all the Greeks. The first was that there was no state worship, in the sense of a pan-Hellenic religion to which all Greeks must subscribe, or any single and exclusive religious worship in any one city-state. The second was that the Greeks showed an amazing degree of tolerance, along with a keen intellectual interest in all religious questions, both tolerance and interest remaining with them throughout the period of their cultural greatness. When the Jew, Saul of Tarsus, presented his new religious doctrine at Athens he could still count upon a Greek audience imbued with religious interest and tolerant to the point of willingness to debate the question of resurrection from the dead.

The Olympian hierarchy of anthropomorphic gods had been formulated by Homer and Hesiod. The Homeric epics and Hesiod's *Theogony* spread through the Greek world as a common Hellenic literary heritage. As these poems became known their gods were accepted as outstanding deities common to all Greeks; and locally one or the other of these gods became the particular deity who protected each city-state and received particular worship as the distinctive deity of that community. They paid the penalty of their origin by becoming poetized creations, with no more religious sanction than could be given in poems which never became a sacred literature and could not lay claim for their teachings to any authority of religious revelation. Religious sincerity must be granted to the city-state cults. It is expressed in the fifth century in magnificent temples, in expensive processions and above all in the dignified statues of the gods created by Phidias and other sculptors of his time. Nevertheless the devotion and worship given to these gods was paid to them as symbols of the glory and the power of the city-state, rather than as deities. Spiritually the small local deities worshiped by the common people struck much deeper. In them and in certain ecstatic worships such as Orphism, the Dionysiac worship and the Eleusinian mysteries, the fundamental religious feeling of the Greeks more truly expressed itself.

In most of the pre-Greek civilizations of western Asia had developed a caste of priests who, as holy men, stood in a closer relation than the layman to the deities whom they represented. In Egypt the Pharaohs were identified with God. The government was theocratic. In marked contrast with this stands the

Greek religious attitude. The priests of the Greek states were mere magistrates, annually elected by and out of the citizen group. The appearance of priestly states is therefore foreign to Greek politics. The Greek religions developed no dogma which each believer must accept. This helps to explain the religious tolerance which was characteristic of Hellenic society. It likewise helps to explain why the Greek religion was so quickly and vitally changed after the conquests of Alexander and the penetration of all western Asia by the Greek spirit. Lacking a common religion believed in by all the Greeks, lacking a sacred book, lacking a theological dogma, lacking the established sanctity and the corporate and vested interests of an old and powerful priesthood, the Greek *polis* religion was altered toward the spirit of the older oriental religions, in which these elements were long and deeply rooted.

In the Homeric poems all of that body of legal customs which had grown up in the Greek tribes to meet the requirements of tribal community life were referred to divine origin. Beside Zeus sat the goddess Themis as his adviser, who was responsible for divine ordinances called *themistes*. During the clarifying movement of the seventh century single lawmakers were empowered in many of the city-states to arrange the laws which were to govern the community. These men were sometimes founders of constitutions and thus originators of public law, sometimes codifiers of customary law. Although the conception of Greek law still retained something of the idea of supernatural origin, a new term arose to express the idea of "justice," the body of rights which appertained to the individual on the basis of the *themis*. This included both natural law (the unchanging laws expressed in the will of the gods) and man-made rules of the social group. These latter rules, originating from men and subject to change by them, could not retain the ideas of changelessness and inviolability. Nevertheless they expressed the sense of "justice" as the will of the tribal citizen body, namely the *polis*. They arose during a period of development from communistic tribal ownership to that of private ownership of property, which attended the change from tribal to *polis* organization. Formulated in a period also marked by the struggle of the lower citizen classes for the right to hold the magistracies, they tend to express restraints imposed upon the *polis* magistrates in their application of the

law to the conduct of the citizen body. Just as the Homeric Greeks personified Themis as a goddess, so the Greeks of the sixth century personified the abstract idea of the laws by which the *polis* was ruled as *nomos* (the law) which incorporated both the idea of the state and the idea of justice for which the state stood.

The complete sovereignty of the laws of the *polis* was expressed about 475 B.C. by the Boeotian poet Pindar in the phrase: "Law (*nomos*) is king over all things." The necessary subjection of the individual to *polis* law and the possibility of a conflict of its dictates with the unwritten custom of divine law gave to Sophocles the artistic motif of his drama, the *Antigone*, written and produced in the middle of the fifth century. The feeling of complete submission to the state and its *nomos* was also expressed upon the tombstone of the Spartan citizens who met their death at Thermopylae with Leonidas in 480 B.C. Though the sacrifice they made was futile as a military measure, it was necessary and unquestioned because it was in "obedience to the orders" of the Lacedaemonians, that is, of the Spartan *polis*. In acceptance of this view of *nomos* as the expressed will of the state, conceived as an ethical entity working to the end of justice, in 399 B.C. Socrates met his death with calmness, despite a personal conviction of guiltlessness. The idea of the *polis* expressed by Pericles in his funeral oration delivered in 431 B.C. (Thucy. II 34-46) has the same ethical content; and in the political teaching of Plato and Aristotle the state is the highest instrument and expression of justice, demanding and setting the environment for the individual morality of its citizens. It is true that only the outstanding thinkers of the late fifth and fourth centuries attained to and held this idea of law and statehood. The sophistic teaching of the individual as the source and norm of ethical standards helped to undermine its validity; and in the period of the completion of the democracy the voice of the *demos*, the concrete group of individual citizens, became dominant over the idea of the abstract "law" as ruler.

Among the separatistic city-states of Greece no general body of Greek law could develop, but a marked tendency is noticeable in the fifth and fourth centuries toward standardization in Greek law through the acceptance of the law codes of the mother cities by the colonies and the practise of many city-states of adopting special features of the laws of some one city. In the Delian League of the fifth century the

code of private law of Athens became the model for many of the cities of the league. A recently discovered papyrus has shown that even in Alexandria in Egypt, founded in 332 B.C., features of the Solonian constitution reappeared in a body of laws applying strictly to the city of Alexandria. Modern jurists are therefore justified in dealing with the city-state codes under the comprehensive term of "Greek law," as embodying certain principles generally accepted by the Greek world. In the period after Alexander the effects of the native law, and the process of amalgamation of Greek legal ideas with those long rooted in the countries then ruled by Macedonian dynasties, resulted in a differentiation of the codes into Syrian-Greek in the Seleucid Empire and Egyptian-Greek under the Ptolemies. The commercial city of Rhodes, however, developed in the Hellenistic period a code of the law of the sea and interstate commerce which was generally recognized throughout the Greek world.

The pan-Hellenic feeling of cultural unity never developed sufficient strength to produce either a pan-Greek nationalism or any great degree of pan-Greek patriotism. The fear of a common loss of freedom might at times unite a large part of the Greek world in defense of interests shared by all; but such unified action was always sporadic and temporary and the feeling of unity which a great crisis might have evoked was quickly dissipated when the danger was removed. The only patriotism which the Greek of the classic period felt or expressed was that toward his city-state. This, however, was intense and absorbing. It finds its highest expression in the words ascribed by Thucydides to Pericles in his oration over the Athenian soldiers who died in the year 431 B.C.: "Such is the state for which these soldiers have died in battle, in consequence of their noble decision not to be bereft of her; and for those of us who survive it is fitting to endure any labor in her service. For this reason I have enlarged upon the character of our state, in order to make clear that our struggle is of far greater moment than the contest imposed upon those who do not share in equal degree in such an inheritance." In the Periclean funeral oration the military glory of Athens is as clearly grounded in her victories over Greek enemies as in those over the hereditary non-Greek enemy, Persia. The Athenian teacher Isocrates in 380 B.C. wrote a pamphlet calling for unity of all the Greeks in a common war against Persia. There are two

essential elements in his discourse: the first, that such a war was the best way to meet an economic-social situation in the Greek world; the second, that *his* state, Athens, had a more legitimate claim to the leadership in such a war than her rival Sparta. Pan-Greek patriotism was not involved. The young Macedonian king, Alexander, inherited from his father a league of the Greeks with the war against Persia as its first objective, and this was formulated as a pan-Greek ideal. The Greeks supported it only grudgingly and through force. Before his death Alexander himself seemed to have substituted in its place a new conception, that of Greeks and "barbarians" as coworkers in a state the culture of which was to be grounded upon Greek elements. Throughout the period of the preeminence of the city-state a pan-Hellenic cultural consciousness existed in the Greek world; but it was a feeling not comparable to modern nationalism. It lacked the element of religious unity found in modern nationalism; it lacked entirely the modern romantic element of love of country in the sense of the land and its scenery. Its devotion was civic. Its love was for the city-state as a political form and for the physical city through which it functioned.

Emphasis upon "individualism" as a marked characteristic of ancient Greek life has become almost canonical in the discussions of many of its best equipped exponents, with a few dissentient opinions. Greek culture must be depicted as highly diversified, but with a uniform background. As viewed from the standpoint of the city-states as corporate units, diversities must be conceded which may be classed as individualizing. In the funeral oration delivered by Pericles in 431 B.C. he makes claim to an individual character and to superiorities of the Athenians and of Athens as against other Greek communities. The comparison with Sparta, which was in his mind, does indeed justify the recognition of two entirely different group ideals as to the place of the state and of its citizens in the economic and political life of the time.

In the sense of a theory of the extreme rights of the individual citizen as opposed to the state, the term "individualistic" cannot fairly be applied to the Greeks of the fifth and fourth centuries. The Greeks did not at any time conceive the legal idea of a group of unassailable rights inherent in each personality, apart from the state. The only freedom possessed by each citizen was political freedom, which came to

him through his participation in the freedom of the state. Preeminently in the fifth century, and still in marked degree in the fourth, the Greek citizen was willing to subordinate himself and his interests to the needs of the *polis*, whether this subordination was to law (*nomos*) or to the group action of the citizens as the *demos*. As a striking example of this the liturgies may be cited. In undertaking the liturgies the wealthier citizens voluntarily took over the expense of maintaining certain public services such as the fitting out of a war vessel for the state, supplying the gymnasia with sand and oil, or training and fitting out the choruses in the dramatic productions at the religious festivals. In the Greek political theory this characteristic attitude toward the relation of the individual to the state is apparent. Within the limits of this subordination of the individual to the idea of the state a great measure of personal freedom, both in thought and in action, was permitted the individual in most of the Greek communities, whether citizen, metic or slave. In Sparta, however, the peculiar conditions of a state organized on the lines of a military body demanded a greater measure of state control as against the individual. But even in the Spartan state and in the city-states of Crete, where a degree of communistic action was developed which differentiated these political organisms from the majority of the Greek communities, the importance of outstanding individuals in determining the course of the political and cultural history of the social group is always evident. The conditions of Greek political and social life in general were such as to give to individuals of marked capacity in all lines a wide scope of expression for these capacities. It is significant that few of the names of the architects of the old Pharaonic temples have come down to posterity. Imhotep, the architect of the *mastaba* of the first dynasty of Pharaoh Zoser, a thoroughly historical individual known to us by a contemporary seated statue, soon lost his human individuality in a divinity which in the Hellenistic period equated him with the Greek god of healing, Asclepius. But scores of names of Greek architects, sculptors, painters, musicians and authors have become fixed in the Greek cultural tradition, and their names and works have been handed down with full appreciation of the particular contribution of each to the technique of his craft. Even in the sixth century this importance of the individual is emphasized in the case of potters and vase painters, the names of both

artists often appearing upon the vase, as on the sixth century François vase in Florence—"Ergotimus made me. Clitias painted me." It is seen in the proud words which opened the *Descriptive Geography* of Hecataeus (*circa* 500 B.C.): "Hecataeus of Miletus speaks thus; I write these things as they seem to me to be true. For the stories of the Greeks are of many kinds and ridiculous, as it seems to me." It is this trait—recognition of the value of the social effort or opinion of the individual of whatever social, political or economic rank he might be—which particularly distinguishes the Greek social experience from that of the peoples who preceded them, and in lesser degree from that of the Romans who followed.

This personal freedom of thought and action is based on the practise, if not the theory, of *laissez faire* in economic and social matters on the part of the *polis* respecting its citizens; on the general lack of pressure of theological dogma on the expression of personal conviction; on a relatively high state of prosperity in the cities engaged in handicraft production in an expanding world of commerce; on the fact that there was no marked social class with exceptional privileges in the industrial cities of this type and that there were marked equality and fluidity of social status, though not of political status, between the classes of slaves, alien residents (metics) and citizens. Equally favorable social conditions did not obtain, however, in the agricultural communities, such as Sparta and Thessaly, which were founded upon the system of exploited serf labor. It was the good fortune of the Greeks that these conditions existed first for them, among all the peoples that have taken part in the development of the civilizations of western Asia and of Europe. It was their merit that they produced a surprising number of able individuals at this particular time. In many fields they were the first to express in written and lasting form things that other individuals may have thought in earlier times. Their enthusiasm, their passion of earnestness, their optimism as to the validity of their reasoned conclusions, are grounded in their priority in expression. It is these qualities of Greek cultural expression which have produced the romantic attitude toward the "joyousness" and the "eternal youthfulness" of the Hellenes of the classic period. The contrary observation that other qualities have dominated the thought of individual Greeks has given rise to an opposed theory, that of the essential "melan-

choly" and "pessimism" of the Greeks. Both views are equally right and wrong; and both have tended to be panegyric in their modern expression.

The claim may successfully be supported for the Greeks that, as distinguished from their predecessors, they introduced into the world the scientific habit of mind. The pre-Greek peoples made many keen observations, and assembled a considerable body of empirical knowledge. They also applied this knowledge to the solution of the practical difficulties which confronted them. Individuals among them likewise approached their problems with marked powers of deduction and an ideal of systematization. Notable among such individual examples is the work of the Egyptian doctor who wrote the famous Smith medical papyrus (in the collection of the New York Historical Society) in the early part of the second millennium B.C. He made the heart the center of the human system, knew the places where the pulse beat could best be taken, organized and wrote down his observations and advice. But this is a single instance in the mass of magical formulae which predominate in the practise of Egyptian medicine. Greek physicians were the first to systematize medical knowledge, to insist that all diseases arise from natural causes, and to establish by observation of numerous recorded cases the probable course of a recognized sickness. Thus they formulated medicine as an empirical science. The Babylonians had assembled a considerable body of astronomical observations; but this knowledge was based on the notion that the gods determined the fate of human beings through the stars, and it was used in the service of astrology. The Greeks systematized their knowledge of the movements of the heavenly bodies and founded the science of astronomy. Where the Babylonians and Egyptians had chronicled consecutive historical events, the Greeks established history as a discipline dealing with groups of related events through the application of critical and recognized methods of approach. In place of the empirical mathematical knowledge which the Egyptians used, the Greeks made a science of mathematics by establishing its laws.

The first appearance of this tendency toward free inquiry and investigation, detached from all theological teaching, occurred among the Ionian cities of Asia Minor in the sixth century. Contemporary with this movement there appeared in the mainland of Greece a revival and

deepening of religious feeling which was unconnected with the public worship of the city-state gods, was peasant in origin and open only to the initiated few. This new religious current is shown in the rise of the Orphic and Eleusinian mysteries and the Dionysiac worship. All of these secret cults were characterized by their promise of a future life to the initiate, by their evangelistic character, by the idea of rebirth through the practise of rites of purification, by the belief in the personal approach of men to the gods in moments of religious ecstasy. Diverging sharply in their whole psychological and mental attitude from the tentative science of the Ionian school of thinkers, their ideas were nevertheless drawn into the movement toward scientific inquiry in the philosophic schools of Pythagoras and Plato. Well into the Christian era the Greek mysteries played an important role in the religious experience of the Greco-Roman world. The Eleusinian initiates had no congregation meetings and formed no social structure. Once initiated they scattered and were absorbed into their own state organizations, carrying with them the spiritual revelation which they had received. The Orphic worshippers, on the other hand, formed a definite social body, observing certain rules of abstention which differentiated them from their fellow beings. But from the societal point of view all the mysteries have one point of common interest and importance. All of them cut through the existing political, clan and family classifications of the time by admitting to initiation citizens, metics or slaves without differentiation.

The first evidence of the new Greek attitude toward the investigation of natural phenomena appeared when Thales of Miletus forecast an eclipse of the sun in 585 B.C. He was followed by a group of men who displayed the same interest in the fundamental problems of nature, and pursued the same general method of inquiry, with all its strength and also its inherent weakness: Anaximander and Anaximenes of Miletus, Pythagoras of Samos, Parmenides of Elea (in Italy), Empedocles of Acragas (in Sicily), Anaxagoras of Clazomenae (in Asia Minor) and Leucippus of Miletus (later of Elea). The insistent problems which they all attacked were these: What is the beginning and source (in Greek the *archē*) of all appearances in nature? What exactly is the form of the universe; and how did it come to assume its present form? In the varying answers which

they gave to these questions they substituted, in place of the mythological cosmology of the Greek religion, cosmic formulae based upon a considerable amount of observation and deduction and on free speculation. Their results agreed in the belief that the "beginning" was one material. They further agreed that this primary source, in whatever form it might appear to the senses, was material. To the earlier thinkers of the group this material was a sentient and dynamic thing, whether water (Thales), an undefinable stuff (the "unlimited" material of Anaximander), air, which by an inherent power of condensation and rarefaction formed the many appearances of nature (Anaximenes), or the sentient "fire" of Heraclitus, which was the god Zeus himself and was itself subject to the universal law of constant change. In the fifth century Anaxagoras was driven to separate sentient force from matter; this force he designated as mind (*nous*), an unemotional intelligence utterly disinterested except in the establishment of order in the universe. In opposition to this, which was potentially a dualistic theory, arose in the middle of the fifth century the school of the atomists, of which Leucippus was the originator, Democritus of Abdera and Diogenes of Apollonia his followers. Atoms moving about in empty space have, by an inward necessity, formed the universe as it is. This atomic theory was a purely materialistic explanation of nature, destined in the Hellenistic and Roman periods to furnish the cosmological foundation upon which Epicurus developed his philosophic doctrine and Lucretius his attempt to free the human mind from the specters of fear.

Out of this Ionian speculative use of intelligence came by divergent lines of development the philosophic systems of the followers of Socrates and an independent movement of strictly scientific thought. The cosmological speculation emanating from Ionia spread quickly, as the names and nativities show, to Italy and Sicily. In this fact are seen the cultural unity of the Hellenic world and the degree of mental intercourse then possible between men of higher intelligence. The movement is not characterized by group thinking. It came through individuals. Pythagoras alone established an actual "school," in the sense of a continuing group. In its replacement, by individual speculation, of the group prepossessions represented in the older Greek religious cosmology, Ionian natural philosophy

displayed quite clearly its scientific character.

Conditions of life as they existed for the Greeks of the fifth century B.C. favored the popularization of the new intellectual movements which had begun in the sixth century. Technical methods in production had become more refined. In all fields, whether economic, artistic or intellectual, the rapid flow of this movement into all parts of the Greek world is apparent. The tendency to use literature as a means of political propaganda or public instruction, which can be noted in the verses of Solon of Athens (594 B.C.), expanded enormously. Crude processional choruses had long been produced by local talent among the peasantry of Attica, and the Dorian communities at the harvest festivals, in which the participants, dressed as goats or satyrs, delighted their neighbors with rustic and ribald humor. Under the hands of the Athenian authors Aeschylus, Sophocles and Euripides, these impulses toward dramatic presentation of some episode in the life of the god Dionysus were refined into a new literary form, the perfected stage drama, called from its origin *tragoedia* (goat song). Its importance in this discussion lies in the fact that the stage drama became an educative force of considerable importance in Greek life and a valuable medium for the expression of public opinion. Often the dramatists included in their plays political comment on the questions of the day as they were being discussed in the streets and markets of the city of Athens. The development of drama was, at the outset, purely Athenian; but the reproduction of successful plays in other cities and their publication for reading purposes gave to the authors a wide scope of influence over the Greek world at large. Comedy, which also developed at Athens, became a medium of violent diatribe and ridicule of political personages, of intellectual movements, of political methods and programs.

The fact that official documents and laws were painted on whitened wooden panels or were cut on stone slabs, and the output of books on many topics, necessitate the assumption of widespread literacy in the Greek city-state organizations of the sixth and fifth centuries. It is therefore surprising to find that the city-states did not interest themselves in mental training or take any responsibility for it, even in the case of their future citizens. There were no public schools. For those who could pay the fees there were private schools, taking care of some hundred and twenty pupils at

times, as we definitely know in one instance. The only compulsion that rested upon a citizen to prepare a son for his place in the state lay in public opinion, feebly supported by a law, ascribed to Solon, that a son who had not been provided with an education was not under obligation of support when his father became old. The subjects of instruction were reading and writing and the learning by rote of passages from the poets, especially from Homer. Beyond this came the playing of a musical instrument of the harp or the flageolet type. In the field of bodily training, since every citizen's son was a potential soldier, the state provided definite open spaces, the gymnasium and the *palaestra* (wrestling ground), and trainers in wrestling, running and jumping, with an overseer of general conduct. Equipment was furnished by the state through the semi-voluntary contribution called the gymnasial liturgy. Specialized training for the trades (*technai*) was obtained through the apprentice system, by contract between father or guardian of a free boy or owner of a slave, and a master craftsman. This system prevailed also in those trades which we differentiate as professions. The practising physician, for example, was a teacher of his *technē* at a stipulated fee.

Nowhere, perhaps, is the effect of the scientific attitude already established in the speculative physical philosophies of the Ionians so clearly seen as in Greek medicine. The practise of treating disease had been carried by the pre-Greek peoples to a fair degree of effectiveness. The claim that the Greeks were the founders of medicine rests upon the fact that they systematized it upon a basis of accumulated and classified observations of the phenomena of disease and made of it a profession with an established social attitude and a code of ethical behavior. Two "schools," that of Cnidos in lower Asia Minor and that of the island of Cos, had already differentiated themselves in the fifth century upon the basis of method of treatment. Of the work of the Cnidian school we have little left except in the criticisms of their opponents of the Coan school. From the Coan school there has come down a considerable body of medical literature, assembled in the early third century by Menon, a pupil of Aristotle. The Cnidian school was said to overemphasize the value of diagnosis and treatment. The Coan followers laid stress upon correct prognosis and the psychological result of the confidence to be engendered thereby in the patient. Something

of the scientific character of Greek medicine at the end of the fifth century and the effect of its methods upon the educated laymen may be seen in the description of the plague which devastated Athens from 430 to 426 B.C. as it is given by the historian Thucydides (II 47-58). He begins with an account of the approach of the disease, from Egypt via Syria to Athens. He then states his purpose in describing the course of the sickness. 'This was to enable people to know about it in case it should again occur; and he gives, as the basis of his exact knowledge, the fact that he had contracted it and had observed the cases of many others who had had it. The medical description of the disease is accurate and detailed. Even more significant is his report of the effect of this disaster, which the medical practise of the time was powerless to combat, upon the mass psychology of the Athenians. "No one was eager to endure sacrifice to gain that thing called good repute, because it was uncertain that one would live to attain it. Whatever was pleasurable for the moment, whatever contributed to this end of pleasure, was accepted as noble and useful. Neither fear of the gods nor laws of men served to exercise restraint, because it was assumed to be a matter of indifference whether one respected them or not, since all men alike were subject to destruction" (Thuc. II 53).

The outstanding figure in early Greek medicine, and one of the great figures in the entire history of medicine, was Hippocrates of Cos, whose best years fell about 400 to 375 B.C. Historical criticism has not been able to take from him the honor of authorship of the Hippocratic oath (*Hippocratic Corpus* IV 628-33 L) which has fixed the ethical standards of the profession since his day. Under the methods of Hippocrates cases were carefully recorded and described. Nowhere is the struggle against the prevalence of superstitious formulae in medicine more clearly stated than in a pamphlet, *On the Sacred Disease*, found among the writings of Hippocrates, but probably from the hand of a clear-headed contemporary. He combatted a tendency among the conventional physicians to refuse to handle epilepsy cases as being of divine origin and beyond the healing power of human skill. Like all other sicknesses, he contended, this also had a natural cause and explanation. Men ascribe anything they do not understand to the gods. If epilepsy is a sacred sickness, so also are the recurrent fevers and sleep walking, since the practitioner is equally unable

to explain them. The author's contention was that all natural phenomena must be approached in the same way. His scorn of superstition mongers, miracle workers, purifiers and other medical impostors was vigorously expressed. Possibly by the same writer is a pamphlet (also handed down among the works of Hippocrates), *On Airs, Waters, Places*, which is characterized by unusual powers of observation and breadth of learning. From personal observations made in a wide range of travels the author of this pamphlet constructed a theory of the effects of climate and soils upon the pigmentation, physical size and spiritual characteristics of men in different regions. He was convinced that acquired physical characteristics were heritable. He believed in environmental influences—that the superiority of the European dweller over the Asiatic was due to the greater harshness of climate in Europe and the greater variability of heat and cold, rain and sunshine. Political factors also, he said, play a part in this result. Wherever monarchy exists there necessarily is slavery. For the souls of people are enslaved under monarchic rule, and they are unwilling to incur danger for the sake of another's power. But the self-ruling peoples, who fight in their own interests, are willing to undergo dangers. He further observed that in Asia wherever men, either Greeks or non-Greeks, are not under autocratic rule but are self-ruling, they are more warlike than their neighbors.

In the medical *technē*, as in other trades, the apprentice system continued to supply the need for specialized and exact knowledge. Here the old Greek family grouping and solidarity continued to display its social usefulness. The father of Hippocrates was a member of the Asclepiad priesthood at Cos. The sons of Hippocrates and his son-in-law followed the profession. Tradition reports that his grandsons and great-grandsons were also physicians of the Coan school. In the fourth century there is a noteworthy movement toward separation of the craft of healing from its traditional connection with the medical experience of the temples of the healing gods and the practise of their priests. Thousands of archaeological finds of dedicatory offerings to the healing powers of the gods made by grateful patients attest, nevertheless, the continuation throughout antiquity of non-rational medical treatment, chiefly by magical cures through healing sleep in the temples of the gods. The important elements in

the history of Greek medicine are the differentiation made between temple treatment and a rationalized medical practise, the development of a craft knowledge and ethical standards by individuals, and the continuation of both knowledge and standards through private instruction by master physicians at definite places.

In the last quarter of the fifth century a group of individuals appeared as traveling teachers of the higher branches of knowledge to all who might have the interest and the money required in payment for their instruction. These were the sophists, professors of knowledge, as opposed to *philosophoi*, which means, literally, "lovers of knowledge." Three circumstances explain their appearance: the lack of public instruction; the greater demands imposed by the growing refinement of technique in all lines; and the public desire to share in the results of the intellectual awakening which was represented in the discussions of the natural philosophers. The prominent earlier sophists were Gorgias of Sicilian Leontini, Protagoras of Abdera in Thrace, Prodicus of the Aegean island Ceos, and Hippias of Elis in the Peloponnesus. Professing the ability to give a complete education in all branches of learning, their aim was to prepare men for practical life, particularly for successful activity in the political life of the time. The growth of democracy, the lack of any provision for a public prosecutor in the legal systems of the time and the want of a recognized legal profession demanded of the individual a knowledge of composition, of argumentation and of methodical and convincing presentation of facts. In meeting these demands the sophists founded the study of dialectics. In the study of language, particularly in its analysis, in the isolation of the parts of speech, and in the rejection of the speculative thought of the physical philosophers, the sophists deserve consideration as a group who furthered the development of the Greek sciences.

The sophists denied the possibility of absolute knowledge. Man is the measure of all things, of the existence of being or the non-existence of non-being. This enunciation of the subjectivity of all cognition was made by Protagoras. Good and evil, as the sophists in general taught, are purely relative ideas; and Protagoras stated that one might set up two propositions exactly opposed and defend each with equal justification. The sophists held that as it could not be known whether or not there

were gods, the "divine" laws in which Pindar, Aeschylus and Sophocles believed had no validity. Critias of Athens asserted that the gods were nothing more than a creation of some clever politician to restrain men from crime. The laws of states, likewise, were mere devices of social utility. Out of this assertion the more radical followers of sophism drew the conclusion that the right of the strong to rule and exploit the weak was a law of nature. Protagoras, however, found a rational ethical basis for individuals and states in the necessities of human association. He asserted (in Plato's dialogue *Protagoras*) that, without a portion of justice and a sense of shame in every man, human society could not hold together. In 443 B.C. Pericles assigned to Protagoras the task of working out the constitution for the colony of Thurii in southern Italy, then to be established. From this circumstance it is clear that the sophists were accredited in their time with something more than the mere academic knowledge of political science necessary for lecture purposes.

The intellectual significance of Socrates lies in the fact that he gave a new impulse to Greek thought out of the impasse into which it had been led by the sophistic teaching of the subjectivity of all human judgments. Socrates was convinced that truth is attainable. The judgments of individuals differ greatly as to the concept of "good," of "bad," of "beautiful," of "ugly." These differences have arisen from lack of clarity in thinking. By methodical analysis through discussion, by isolation of the essential elements of each concept, by agreement upon these essentials, the underlying truth of each judgment might be attained. Concepts thus attained Socrates held to be valid, and eternally so. Knowledge, therefore, could be both learned and taught. Through the definition of the "good" as that which is good for the person (advantageous in the best sense), Socrates came to the conclusion that goodness is the same thing as correct knowledge. The task of leading his fellow citizens along the pathway of correct thinking, particularly in its application to political activity, Socrates conceived as a mission imposed upon him by an irresistible inner impulse. He stood upon the same ground as the sophists in regarding the studies of the physical philosophers as useless, in his belief that the human being should be the sole object of investigation, and in the practical aim of educating the citizens of the state for political

life. He differed from the sophists completely in the method by which he attempted to reach this end, through discussion rather than by *ex cathedra* pronouncement of opinions. The "Socratic method" was of considerable importance, therefore, in furthering the development of thought. Socrates wrote nothing. He developed no philosophic system. It is through his pupils that he became the founder of Greek philosophy in its broader sense, as a metaphysical system freed from the limitation to cosmological questions which had characterized the earlier Ionian philosophy. Through his attempt to educate his fellow Athenians toward true thinking, therefore toward virtue and efficient citizenship, he injected the problem of ethics into political theory and thus into philosophy.

In the Iranian dualistic religious teaching the powers of good and evil strive in the physical world for mastery; and this strife is waged also in the heart of man. From Iranian Zoroastrianism this doctrine was taken over into Christianity and so dominates modern popular moralism. To approach the social conduct of the ancient Greeks with this preconception would lead not to a correct understanding of their attitude, but rather to a blind condemnation of practises which Greek society did not condemn and which Greek law, in many instances, publicly recognized. The entire problem of sexual purity, for example, which dominates Christian morality, fell away from their ken. "Purity of heart," in its sexual application, had no meaning to them. They never recognized thought in itself as evil. In precept and practise, beginning with the traditional doctrines of the semi-historical Seven Wise Men of the seventh and sixth centuries, the ideals were temperance, self-control, balance, the *mēden agan* (nothing in excess) inscribed on one of the temples at Delphi. In the actual Greek life of Plato's day sexual relations outside of the institution of marriage were permitted and expected. Marriage, according to Demosthenes, is an institution for producing legitimate children. Concubinage was expected, the offspring of concubines legally acknowledged and legally protected in their freedom if the mother were free. In Greek society of the fifth and fourth centuries homosexualism was frankly recognized.

Equally alien to modern Christianized morality is the Greek practise of infant exposure. In Sparta the right of the ephors to determine whether a child should be permitted to live or

should be exposed, was a usurpation on the part of the state of the primitive family right of the father. At Athens, as in other Greek city-states, the old right of life and death held by the head of the family was maintained with respect to the newborn infant until diminishing population, combined with the Christian ideal of the sanctity of human life, did away with the custom of exposure.

Accepting the method of Socrates and his belief that absolute judgments were possible, his pupil Plato, fundamentally a visionary and a great artist, attempted an adjustment of the difficulty which seemed inherent in the Socratic theory of cognition because of the illusory nature of sense perceptions. By a transcendentalizing process and with captivating imagery he established a world of super-concepts, superimposed upon this world of concepts. To him the realm of super-concepts was the realm of actualities (*ideai*, "forms"). The material world contained mere quasi-truths, reflections of the everlasting realities, impaired and distorted by the bodily senses. By adding the Pythagorean doctrine of pre-existence he could assume that those who had in higher degree the finer qualities of soul retained a dim memory of the actualities which they had seen in a pre-existent state. By intuition, by contemplation of these actual things, rather than by processes of reasoning, they might reawaken the memory of the *ideai*. Only such persons, true philosophers who had attained to self-knowledge, were truly competent to rule. In one of the letters ascribed to Plato (*Ep.* VII 326 a-b) a passage occurs which explains the political orientation of his philosophy. By the conditions of his birth and material welfare, an active political career in the Athenian state would have seemed the natural outlet for Plato's energies. At first he had been eager to take up active political life, but he soon perceived that all the city-states were badly governed and that the voting of good laws, under the prevailing conditions, was a matter of chance. He was driven to the conclusion that justice for the state and for individuals depended upon the study of philosophy. Human ills would not cease, he thought; until either philosophers who were trained to think straight and truly should come to hold the magistracies, or until the magistrates should become true philosophers by the interposition of some divine agency.

Out of this belief in the possibility of applying philosophy to the government of society Greek

philosophy assumed its complete form under the shaping hands of Plato and his pupil Aristotle of Stagira. The Academy founded by Plato in the belief that through philosophic study true statesmen might be trained, accomplished little, however, toward this end. The importance of the Academy and of the Lyceum later established at Athens by Aristotle is to be gauged by their history as organized centers of intellectual life in antiquity. In this respect their influence endured for a thousand years until, by order of the Emperor Justinian in 529 A.D., the philosophic schools at Athens were permanently closed.

Political thought was, from the outset, a fundamental part of Greek philosophy. Socrates had laid the foundation for the development of ethics. In his discussion of the problem of the good citizen he had introduced the idea of man as an ethical being. Plato's contribution to this branch of philosophy was the application of the criterion of ethical value to the social group, the placing of the good citizen in a state organization the aim of which was justice. Ethics thereby received its orientation in the general field of philosophy as a branch of political science; and political theory, which received both a keener analysis and a sharper and more scientific definition through Aristotle, acquired its characteristic ancient stamp as a systematization of social ethics. The practise of politics has constantly and widely deviated from this original philosophic standard. But in its theoretical treatment, whether the state be regarded as the end and embodiment of social morality or merely as a means of attaining certain practical objects such as public security, public order and general material welfare, political science has never departed completely from the Platonic conception of it as political philosophy.

Fundamentally Aristotle had a scientific mind. His tremendous powers were best displayed in his classification of the fields of knowledge embraced within the comprehensive designation of philosophy, in the establishment of scientific terminology, in the analysis of methods of approach, in the collection and arrangement of empirical facts, and in the hypotheses which he established on the basis of observed phenomena. In his metaphysics he remained under the influence of Plato's teaching of the "true forms." But it is characteristic of his mind that he sought these "realities" not in a supernatural, transcendental world with no bridge existing between it and the material world, as Plato had

done. These "realities" existed, for him, in the world of matter, immanent in the things of the sensory world. Equally characteristic is his treatment of the state (in his *Politics*). He starts with the proposition that man is inherently a social animal. Happiness can be obtained only by ethical activities of the soul; and the realization of a good life, and therefore of human happiness, is possible only in the setting of the state. The state form practically adapted to this realization is the city-state of the Greeks. In his *Politics* it is not the purpose of the realist Aristotle to describe a utopia but to formulate out of his knowledge of existing states a workable institution which will permit the practise of the "good life." Characteristic of his method is the fact that he had studied one hundred and fifty-eight separate state forms of the world of his day. He had described them in pamphlets, of which only one, *The Athenian Constitution*, has been preserved for us, found in the dry soil of Egypt and first published in 1891. The portion of his *Politics* which won for Aristotle the title of founder of political science is his division of the existing types of city-states into monarchy, aristocracy and polity, with their corresponding perversions—tyranny, oligarchy and democracy. This classification has been criticized as being based upon a purely quantitative principle applied to the ruling power. The criticism is valid from the standpoint of the inadequacy of the classification for present-day uses. If, as is more legitimate, Aristotle be regarded in the light of his own time, the criticism is found to be based upon the misapprehension that he was dealing with all the political forms extant in his day. He restricted his discussion, in fact, to the city-state form, neglecting the great territorial monarchies and the federations of his time. His division of the departments of government on the basis of function (*Politics* VI 14) into the deliberative, executive and judicial bodies, still retains its validity.

Social morality, as taught by both Plato and Aristotle, still betrays a fundamental tribal attitude in that the morality of the state does not transcend the relations of the individual citizen and his own state. In external politics Plato (*Republic* 469-474) warns the Greeks that only the barbarians are to be considered as natural enemies. Wars between Greek states are to be regarded as fraternal struggles in which extermination, wasting of the countryside, enslavement of a city and its inhabitants, are

not permissible. But this is a mere concession to the idea of the cultural unity of the Greeks so much discussed in his time. Aristotle declared that without military power and the exercise of this power against outsiders the state could not maintain its sovereignty. The struggle of one Greek state for hegemony over other Greeks was justified in his eyes if the rule thus established was made advantageous to the subjected Greeks. The conquest of non-Greeks was a natural right falling to the Greeks because the barbarians were their inferiors and thus by nature destined for enslavement to them. The philosophers' theory of political ethics contained no discussion of right and justice as between Greeks and non-Greeks, or even, in the fundamental sense of international law, as between Greek city-states. A theory of international ethics had not yet arisen.

Significantly the word "history" comes from the Greek word *histerein*, "to learn by inquiry," used by Herodotus. A curiosity of mind in respect to the peculiarities of peoples and places is noticeable in the few remaining fragments of the early Greek chroniclers of historical events, Hellanicus of Lesbos and Hecataeus of Miletus. This trait distinguished the early Greek annals from the lifelessness of the records kept by the pre-Greek peoples of antiquity. Hecataeus had applied the criterion of personal criticism to the tales of the past which had come down to him, but he was still "a writer of tales" (*logographos*). Historical research and methodical skill in its presentation—the conscious method and discipline as well as the art of history—are creations of two Greeks of the fifth century B.C., Herodotus of Halicarnassus, and Thucydides of Athens. Herodotus in his account of the Persian wars is not without marked subjective tendencies, one being to glorify Athens, a second to defend the oracle at Delphi against the accusation of having prepared a favorable position for itself in case of a Persian victory. Herodotus was unable to discern the political, economic and social forces which determine historical events. As in the Greek tragedies of his time, the will of the gods dictates the outcome of human events. With ruthless envy the gods strike down those whose overweening greatness has irritated them, as with their lightning bolts they strike the tallest trees. This is the explanation which Herodotus had to offer of the unexpected defeat of the Persian by the Greek forces. He had traveled widely in his earlier years, collecting materials on the

characteristic social customs of different peoples, in the manner of Hecataeus, and on their past history, in the manner of another Milesian *logographos*, Dionysius. He was the first writer who conceived the idea of investigating a great historical problem and of presenting his results as historical literature. He was fortunate in the fact that the problem—the series of wars conducted against the Greeks by the Persian kings Darius and Xerxes—happened to be a crucial one in the historical life of the Greeks. This combination of circumstances, aided by his honesty of intent and peculiar charm in narration, have given him the title of the “father of history.” His earlier ethnographical studies as *logographos* have been patched into the body of his narrative as they seemed to be applicable. His purpose, as stated in his brief preface, was to save from oblivion the great and wondrous deeds of both Greeks and barbarians, and in particular to present the reasons for the war (historical causes). The causes which he presents are trivial; and he gives three conflicting reports, the Phoenician, the Persian and the Greek, without drawing a conclusion based on personal critical analysis. Nevertheless, by dealing even naïvely with causes, he isolated and consciously stated one of the essential elements in the investigation of historical sequences.

Thucydides wrote on contemporary events, and in particular on the Peloponnesian War, in which he was himself at first a participant. After his banishment from Athens in 424 B.C. he remained a keen and indefatigable observer of the course of the war. He was the first writer of historical events who analyzed critically the sources of his information and passed judgment on their validity. He realized the untrustworthiness of oral tradition, of the statements of eye witnesses, of his own memory and consequently of the memories of others (Thuc. I 22). Where Thucydides used official documents which have come down to us inscribed upon stone, he stands the test of general accuracy with credit. He distinguished the alleged reasons for the war from its fundamental or “truest” cause. This he considered to be the increasing power of the Athenians and the fear which it inspired in the Lacedaemonians. He was conscious of economic forces in history (Thuc. I 23). The gods, the oracles, all supernatural paraphernalia, are eliminated, except as the belief in these may produce a demonstrable effect upon the course of events through the psychological reactions of indi-

viduals or groups. He eliminated from his narrative everything of a purely episodic character which seemed to him to be unimportant, consciously sacrificing historiographic interest to historical importance. His careful methods in deduction from data which he had tested and accepted as trustworthy may still be profitably studied by historians. He was the first critical historian and one of the best.

In the business life of the Greek-speaking world the use of coined money as against barter economy had gone forward in the fifth and fourth centuries with amazing rapidity. The government of the great Persian Empire, covering southwestern Asia and Egypt, also coined money. But in the persistence of exchange in kind, in the custom of treasuring its surpluses of revenue in hoards of gold and silver, in the continuance of state monopolies inherited from the past, in the state ownership of great stretches of the arable land held as royal domain and worked by semi-serfs, the Persian Empire was unmodern in comparison with the Greek city-state world. In both agricultural and industrial production many survivals of the old royal and temple household (*oikos*) system remained, sanctified by centuries of custom. In Greece production and transportation were largely in the hands of private individuals, with little regimentation by the city-states as against their subjects. Private ownership of real estate and agricultural land was the rule in the urban industrial communities, although this general condition did not prevail in other places such as the socialized military state of Sparta, or in non-industrial communities like Thessaly and Macedon. In backward communities and on the periphery of the Greek world, in the more distant colonies of the Black Sea, for example, the functions of production, transportation and merchandising were, no doubt, often combined in one person. Of the industrial cities Athens was among the most important, as it is also the one best known to modern investigation. The Athenian situation may be regarded as representative of that of other large cities and of many smaller ones. In these communities investment opportunities for surpluses of capital accumulated in individual hands were chiefly farm lands (for olive and vine growing in Attica), handicraft industries, slaves trained to some trade and rented out to entrepreneurs, or loans made to professional merchants and owners of ships to finance their commercial enterprises. Since the city-state laws forbade

metics to own real estate, the accumulations of those metics who had been able to acquire any wealth were largely invested in small industries. The less fortunate earned their livings as skilled workmen or as petty tradesmen or engaged in transportation backed by loans for the merchandise which they carried. At Athens the overseas transportation was largely in their hands.

The importance of wealth as reckoned in terms of money and its interest-bearing capacity increased greatly in the Greek world of the fourth century. The money changer had necessarily been a prominent figure in all Greek markets because each of the multitude of city-states maintained its own mint and held jealously to its own coinage system as an important element of its independence. The extension of money-changing houses into banks occurred at Athens. It was largely due to a metic named Pasion and the successor to his business, a freedman named Phormion. Pasion established a deposit bank in which he received money and valuables from customers, paying interest on certain types of deposits. The accumulations he lent at interest. An important element in the financial transactions of this bank, and of others which rapidly arose in competition, lay in the technique of its bookkeeping by which payments of one customer to another could be made by transfer, on personal order, from the one account to the second. This was quickly extended to payments between customers of two different banks. Pasion made loans on valuable articles deposited in his storeroom, in the manner of a pawnbroker; and he was also a manufacturer on his own account and owner of his own shipping facilities. In the generation which followed him, however, banking became a more specialized department of business life.

Naturally there was considerable public suspicion of these early bankers, augmented by several disastrous endeavors in this new field of enterprise. This feeling is attested by the speeches of lawyers in suits entered against the bankers. Nevertheless the development of banking progressed rapidly. Either in the form of a state monopoly of banking enterprises, as in Hellenistic Egypt, or in private hands, as under the Roman Empire, deposit banks became an important feature of the economic life of antiquity. The social effects of the new opportunities thus afforded for safe reinvestment of accumulated surpluses cannot be traced with accuracy. It is safe to assume that the growing

differentiation of propertied classes and the poor was affected by it, and that the new regard for money as working capital influenced the old willingness of the citizen classes to assume semi-voluntary tax burdens such as liturgies for the navy and for the public gymnasia. The philosophic-political theorists of the fourth century were entirely opposed to the new economic order. They had found it possible, though with important changes, to adapt the political form of the existing city-state to their hopes. Their opposition to the current economic order was more complete, their suggestions of change were much more sweeping.

In the legislation of Solon (594 B.C.) citizen obligations and privileges at Athens were still based upon a classification expressed in terms of income in kind (500 bushelmen, etc.). At the opening of the Peloponnesian War in 431 B.C. the adjustment to the new complexities of business, both private and public, had been successfully made. Records of the Athenian state are available from 454 B.C. onward which show that a practical system of state accounting had been established, based upon tribute and taxation paid in coined money. Pericles, as head of the administrative and military board of the ten *strategi* (generals) at Athens, had reorganized and simplified the treasury system, reducing the number of the treasury chests and concentrating responsibility for payments and records (decree of 434 B.C. published in Hicks and Hill, *Greek Historical Inscriptions*, no. 49). Discussions of economic problems began to appear thereafter which display a new understanding of the importance of economics, especially of state and private finance. Among these are the *Oeconomicus* of Xenophon and the pamphlet *On Ways and Means*—a suggested scheme for increasing the revenues of the state—which appears among his writings. Isocrates, an Athenian teacher of composition and rhetoric of the fourth century, in urging the Greeks to cease their city-state wars and combine for an aggressive war against Persia, was definite in his insistence that some of the economic and social ills then prevailing in the Greek world could be cured by the conquest and exploitation of the western part of the Persian Empire. The new knowledge of the importance of business expressed itself in the appearance of the word *oikonomia*, which means, literally, "household management." Despite their understanding of business relations in social life, the Greeks did not establish economics as a separate discipline.

In their treatment it remained consistently a branch of the study of political science, which again was not abstracted from the general field of philosophy. This orientation within a metaphysical system explains why the economic theories of Plato and Aristotle are so completely colored by the ethical aims imposed by them upon the state as the embodiment of justice.

Both in the political practise of the city-states and in the political theory of the philosophers the purpose of the polity was to look after the material and moral welfare of its citizen group, but of this group exclusively. Protection of the rights of the classes of metics and slaves was subordinated to the advantages of the citizen body. One effect of this differential treatment appears in the early custom of distributing the financial surpluses of the state to citizens only. A later and more practical application of the idea was made by Pericles when he introduced payment for citizen service in the *boulē* and on the juries. This policy finds its rational justification in the democratizing tendency of the Periclean party, which aimed to equalize citizen participation in state affairs among all representatives of the citizen body, whether rich or poor. The introduction by Pericles of payment, to citizens only, of the fee required for admission to dramatic performances, exemplifies more clearly the old attitude of the privileges of the tribal group.

The economic knowledge of the philosophers of the fourth century, as represented by Plato and Aristotle, included the definition of wealth as value in use or in exchange, and an understanding of the difference between material wealth in money or goods and immaterial wealth represented by trained ability in some craft. Plato is definite as to the advantages of division of labor in the handicrafts and is insistent on technical specialization in the financial aspects of business. In his reaction against the social values of the new commercialism he attempted to eliminate both wealth and poverty because of their disastrous effects upon the ethical well-being of the citizen classes. He could not do away with mobile capital entirely, but would permit its accumulation only to an amount four times the value of the land allotment to each citizen. He would not permit citizens to engage in commerce or handicrafts. He would permit them to engage in agriculture but not as a means of gain beyond a livelihood. Surpluses of agricultural production were to be at the disposal of the state. Prohibition of the

use of gold and silver money by private individuals, of loaning at interest and of business on credit—these demands were designed to strike at the roots of the capitalism of his time. Economically the *Republic* and, in somewhat less degree, the *Laws* of Plato represent the attempt of a disillusioned mind to escape the evils of his own time by reverting to obsolete conditions of a past which could, in fact, no longer be revived.

In the political theory of Plato and Aristotle an attitude of contempt toward handicrafts and trade was established which dominated philosophic discussion, in its economic aspects, for three hundred years. Agricultural work alone was regarded as worthy of a citizen, the practise of the trades being relegated to non-citizen classes. This theoretical attitude toward industrial labor has often been accepted as representing a social feeling widespread among the general public of antiquity. Such was not the case. Where he was not under the compulsion of his general scheme Plato himself in his dialogues shows a high regard for good craftsmen as exemplifying purposeful devotion to the task in hand and a knowledge of the methods of reaching their ends which should be equally applied in statecraft. This more rational attitude toward labor goes back, no doubt, to Socrates who was himself a trained stonemason.

The political and social classification of citizen and non-citizen members of the perfected state in Plato's *Republic* and *Laws* is a free adjustment of actually existing institutions, especially those of the backward state of Sparta, to prevailing conditions of Greek life and to the necessities imposed by the larger metaphysical-ethical scheme in which this perfected state was set. Acceptance of the prevailing assumption of differences in the innate capacities of men seemed to give to the classifications of the theorists a rational and scientific justification (*Republic* II 370). The soul, says Plato, has three distinct faculties, those of reflection, of courage and of desire, or appetite. In accordance with the dominance of one or another of these parts of the soul, the citizens are to be divided respectively into three classes, the philosopher rulers, the warriors and the producers. The normal condition of warfare among the Greek city-states is accepted as a constant; and the task of the class of warriors is to provide for the defense of the state. The communistic feature of state support for the two upper classes and their separation from all connection with

productive enterprise is an adaptation of Spartan conditions. The elimination of the class of producers from any connection with the political or military functions, their reduction practically to a state of helotage, is Spartan. So also is the requirement of state control of the rearing and education of citizen children.

III. THE HELLENISTIC PERIOD. Outside the circle of the Socratic followers many other thinking men had lost the belief in popular rule by the citizen group which had motivated the internal politics of Pericles. By the historical student it may be questioned, as well, whether the entire system of the particularistic city-states had not proved itself unsuited to meet the changed needs of the Greek world. From the beginning of the Peloponnesian War to the battle of Chaeronea in 338 B.C. the tendency toward unity in larger groupings and the old ideal of the self-sufficient city-state had been pitted against each other in constant and destructive warfare. Hegemonies, established by *force majeure*, succeeded one another rapidly and passed away without justifying themselves by any new political idea capable of replacing the city-state separatism. One practical and promising effort toward solution was, however, attempted in the fourth century. This lay in the formation of localized federations of city-states in various parts of Greece, among them the Chalcidic and Boeotian Leagues. These combined complete autonomy and freedom from interference in local administration and legislation with the possibility of unified action over larger areas. It is a tribute to the political realism of the Greeks that they worked out in these leagues the practise of representation in the federal legislative body and in federal administration on a basis roughly proportional to the population and the tax paying and military strength of each unit. It is a singular fact that neither Plato nor Aristotle mentions the idea of the federations of city-states which had sprung up about them. Just as they failed to envisage the possibility of the life of happiness and moral elevation, the "good life," amid the new economic realities of the actual world of their time, so also they clung to the outward form of the city-state, though vitally changing its inner content. This inability to conceive the state except in the form of the small *polis* may be explained by their purpose, which was to place the individual as an ethical being, the state form being merely the organism in which

the individual must meet these problems, and therefore only a necessary side issue to the major problems. The city-state was the form within which Greek civilization had developed, and in their minds, perhaps, the only organization suited to the temperament of the Greeks with whom they were concerned. These suggestions may offer a satisfactory explanation of the fact that Plato and Aristotle did not deal with the possibilities which lay in the city-state leagues of the time.

When he had the Greek peninsula securely in his power (338 B.C.), Philip II of Macedon paid his tribute to the reality and power of the city-state as a Greek ideal and to the possibilities inherent in a federal organization of city-states by uniting all of the Greek states except Sparta in a comprehensive League of the Hellenes. There is little doubt—and this applies equally to Alexander at the outset of his career—that he intended to make the League of the Hellenes of essential service in the world which might be created as a result of their activities against Persia. Alexander's conquest of the Persian Empire resulted, after his death, in bringing under the sway of dynasties of Macedonian nobles a great territory with old and well established cultures. Their peoples had long been accustomed to the government of autocratic monarchies. Alexander had wisely adopted autocracy as the necessary basis of his rule over his Asiatic and Egyptian subjects. In this he was followed by his Macedonian successors, the Seleucids in Asia and the Ptolemies in Egypt. In Macedon, however, the monarchic power was never able to discard the limitations upon it which were traditional to the country.

Although in the new conditions of the Hellenistic age the city-states declined in political importance, their cultural significance still persisted. We know that Alexander requested his former tutor Aristotle to write two treatises for him, both lost to us, one on *Monarchy*, the other on *Colonization*. These were the two principles which he used in his great plans for the world he had conquered—monarchy as the form which Greek rule was to take in the newly conquered world, and colonization of Greeks and Macedonians as the means of maintaining that power and disseminating Greek culture within its bounds. It is a splendid tribute to the city-states of the Greeks, and to Alexander's understanding of their value, that he organized his colonies from the outset in the city-state form, each with its Macedonian-Greek citizen

body, its elected officials and its electoral-legislative assembly. It was a recognition of the fact that the Greek culture which had been created in the city-state could only live and work effectively in the atmosphere which had produced it. The independence of these new city-state creations was one of mere local autonomy and freedom from the oversight of provincial governors; but as a concession to the cultural value of the city-state and to the intensity of the Greek feeling for it, its use by Alexander is significant. In this policy of colonization by city-states Alexander was necessarily followed by his Seleucid successors in Asia. Their territory included Asia Minor, in which free Greek cities had long been established and the demand for independence remained alive. The numerous cities which the Seleucids founded in Syria naturally were in close contact with these older Greek cities. The Seleucid foundations, in consequence of this proximity, developed and maintained a considerable amount of independence as against the Seleucid state in the second century B.C., when the kingdom of Syria was breaking down under the pressure of Roman advance from the west and Parthian attack from the east.

In Egypt the situation was entirely different. Outside the old free city of Naucratis at the mouth of the Nile, Greek politics were unknown. Alexander had founded the one Greek city of Alexandria, giving it the customary government of a city-state. It became the residence city of Ptolemy I. As the royal residence of an absolutistic monarchy of the old Pharaonic type its city-state freedom was from the outset a mere shadow. Only one other free Greek polity was founded by Ptolemy I, at Ptolemais in Upper Egypt. Macedonian and Greek settlers came into Egypt in swarms, attracted by the wealth of the country and by the amazing opportunities for advancement which the bureaucratic and military service of the Ptolemaic state offered them. The Greeks recruited for the Ptolemaic armies throughout the countryside were settled as holders of land allotments. Though many of the Greek immigrants lived in cities and towns and established therein Greek temples and the customary externals of a Greek cultural life, these cities and towns did not become self-ruling Greek polities. In those territories, however, which the Ptolemies held outside of Egypt, they were compelled to compete with the Seleucids, and their colonization took the customary form of the "free" city-state. Al-

though the city-states of the Hellenistic period retained the organs of the democratic *polis* and continued to pass laws and resolutions, it is obvious that their actual dependence upon the great autocratic monarchies left them only a limited range of independent action. They serve, however, as a recognition, by Alexander and his followers, of the cultural value of the Greek *polis* and of their belief that the life which the city-state had created could be best perpetuated through its agency.

It is clear that the old Greek type of *polis* patriotism must, in the new world conquest, give way to a wider conception. The result is seen in the rise of a supranationalism which the Greeks called cosmopolitanism (world citizenship). It corresponded to the new cultural situation which actually existed in that part of the world lying within the eastern coastline of Spain and the Indus River. One language, the Greek, in a standardized form called the *koinē*, would carry a man from its eastern to its western limits. This is seen in a recently found Greek papyrus of the second century after Christ, in which an Egyptian proclaims the praises of the Egyptian-Greek syncretized worship of Imhotep-Asclepius. He had translated into Greek the tale of his religious experience, explaining his reason by addressing the god thus: "Every Greek tongue will proclaim your story and every Greek man will worship Imouthes, son of Phtha." Other agencies likewise tended toward a certain standardization of external aspect in this Hellenized world, the Hellenic forms being the standardizing and universally accepted elements. The urban communities which were not Hellenic city-states were eager to obtain the outward signs of Hellenic culture. When Antiochus IV, the Seleucid king, was in Syria and Palestine, envoys from many communities came to him petitioning that the king set up a gymnasium, form a body of *ephebi* (semi-military clubs with a definite social standing) and register the inhabitants of these communities as Antiochenes, which meant that he was to establish their cities as autonomous city-states under the name of Antioch (*Maccabees* II. 4: 9). In 58 B.C. Julius Caesar found that the records of the Helvetians of Switzerland were written in Greek letters. The apostle Paul, preaching in Lystra, a town of southern Asia Minor, made his remarks in the *koinē* Greek which the local population understood. His hearers reverted, however, to their own Lycaonian dialect when excited by a faith cure

performed by Paul. The tendency toward universalism expressed itself in the philosophies of the time, particularly in stoicism, and in the appearance of histories which dealt with the general world conditions at a given time rather than with a single country or people. The new historical outlook appears notably in the historians Polybius and Posidonius, and it is later marked in the work of the universal geographer Strabo.

It is true that Greek culture, in the period from Alexander's conquest to the establishment of the Roman Empire, attained a position of preeminence over the minds of cultured men in modes of thought and modes of expression such as no previous civilization had approached. This preeminence differentiates itself from that later won by Islam in that Greek culture penetrated all the Semitic and old oriental areas which Islam later conquered and in addition bridged successfully the ethnic and cultural divergences which separated the mental world of north Africa and southwestern Asia from that of Europe. This feat Moslemism could not accomplish. In the latter half of the third century B.C. a king of Ethiopia (modern Sudan) is reputed to have "had some tincture of Hellenic education" and to have studied philosophy (Diodorus III 6). In the process of their spread the Greeks and Macedonians themselves were in time gradually assimilated by intermarriage with the local populations. In Egypt they became Greco-Egyptians, in Syria, Greco-Syrians, in distant Bactria, Greco-Bactrians. The mother of Antiochus I, son of that Seleucus who founded the Macedonian dynasty which ruled in western Asia for two hundred and fifty years, was an Iranian princess of Bactria. Although the Jews on the whole resisted the intrusion of the modern Greek culture of the time with fanatic zeal and although intermarriage with Greeks must have been extremely rare among them, the question of the adoption or rejection of Hellenic life became the central political question in Palestine in the second century B.C. Under Antiochus IV of Syria (176-164 B.C.) two of the high priests of that time bore Greek names, Menelaus and Jason. Through the Greek papyri it is now possible to follow in Egypt the actual process of intermarriage between Greeks and native Egyptians. The net result is that after 150 B.C. the appearance of a Greek name in Egypt implied only that its bearer was of the upper and educated class. The Ptolemaic ruling family maintained

its blood untainted by Egyptian elements. Nevertheless the surrender of this dynasty to non-Greek standards is clearly shown in their adoption for political purposes of the old Pharaonic custom of brother-sister marriage. The custom in one authenticated instance was also followed by a Seleucid king. To the mind of the Greeks before Alexander's day this was incest, and as such abhorrent. It is significant of the local differences which continued to exist in the Hellenistic world that this practise was never adopted by the Macedonian kings and was never regarded with favor in Greece itself.

In the process of its spread over the ancient Near East and its acceptance by the preponderant body of natives living there, Greek culture necessarily suffered vital changes other than those exhibited in the substitution of universalism for local patriotism and the general acceptance of governmental absolutism in place of city-state freedom. Such changes might be the result of original Greek conceptions which were altered in the process of adaptation of the Greeks themselves to circumstances which were fundamentally different. They might result from the adoption by the Greeks of older ideas of the pre-Greek Orient. Or they might be the outcome of a combination and amalgamation of both Greek and oriental tendencies into a new belief or a new approach to the problems of life. The process and result of the transformation of Greek culture into Hellenistic culture is clearly seen in the changes in religious life and thought. New to the Greek world and significant of the process of derivation from both Greek and oriental points of view, is the rise of the Hellenistic king-god cult. Alexander the Great was the first Greek monarch to receive and to demand worship as a god. In 332 B.C. he entered Egypt, then a satrapy of the Persian Empire, but smoldering with the spirit of revolt. Alexander was hailed as a liberator. The country fell to him with no resistance. His most significant act was to take a journey of some twenty days to the temple of Ammon in the great western oasis of the Libyan desert. Upon his arrival there he was hailed by the priests of the temple as the son of Ammon, whose oracle had a prestige in the Greek world almost equal to that which it enjoyed among the Egyptians. To the Egyptians this act of the Ammon priesthood was a necessary and customary procedure in the legitimizing of their Pharaoh, by recognition of him as son of the sun god. Eight years,

later Alexander sent out from Susa a demand to the Greek city-states that each city place him among their city gods. The origin of this demand, to which the Greek cities agreed, is purely Greek. The distance between gods and men had never been great in the anthropomorphic polytheism of the Greeks. To add one more god to the list of their divinities was not impossible or even difficult for them. The founders of colonies had customarily received the honor of cult worship after death. Sophocles, the dramatist, had in like manner been honored with a shrine and a cult worship. Isocrates had written to Philip of Macedon that if he should unite the Greeks and lead them in a national war against Persia he would indeed be a god. Aristotle had taught that a gifted ruler of incomparable virtue was like a deity on earth. Alexander's demand from the Greek states was therefore Greek. It implies nothing as to any personal conviction on Alexander's part of his own divinity. The explanation is now generally accepted by historians that the measure was political. It relieved him of the embarrassment caused by the independence of the Greek city-states, which Alexander had himself recognized in the League of the Hellenes and of which, as *hegemon* of the league, he was the defender. If recognized as a god in each of the city-states, he was thereby placed above the laws which its citizens might pass. The whole method and attitude toward this Greek divinity by decree of man differed from that which had created the divinity of the Pharaoh. The Greek ruler-god became such by virtue of an apotheosis. The Egyptian god-ruler was such by special investiture and by an act of divine grace.

Greek city-state polytheism had suffered by the attacks of Ionian physical philosophy in the sixth and fifth centuries. The followers of Socrates in the fourth century had assumed the function of ethical guidance of individuals for which the city-state religion provided no machinery. The *polis* had lost its importance as a political factor in the Greek world. With the decline of the city-state, the *polis* religions also lost the remainder of their spiritual hold upon the Greeks. The Macedonian Seleucids who ruled over western Asia, the Greek kings of Bactria, the Macedonian Ptolemies in Egypt, were monarchs in countries which had been accustomed to religious control, exercised by the state and guided by strongly established priestly classes. The tendency of the times, both by natural growth and by conscious effort

of the rulers, was toward the growth of syncretistic religious forms which might appeal both to the Greeks who colonized Egypt and western Asia, and to the natives, and give to the two ethnic elements a common ground of worship. In this process of amalgamation, identification or equation of a Greek god with an oriental god, it was the spirit of the oriental deity which dominated.

The best example of such a growth was the worship of Sarapis, which spread widely and far beyond the boundaries of Egypt where it originated. Out of a previous worship of the dead Apis bull as Osiris-Apis in the ancient city of Memphis, evolved the Greek divinity Sarapis as a god of the underworld. There is some reason to believe that this cult was a creation of Ptolemy I as a part of his religious-political policy. Certainly the cult was a matter of deep interest to the first two Ptolemies. Promising immortality, sometimes in the triad worship of Isis, Sarapis and Anubis as at Delos, sometimes alone, Sarapis attracted worshipers over the Greek world; and his cult was destined to endure for seven hundred years, until Christianity was strong enough to eradicate it.

With the conquest of Persia Iranian religious ideas began to penetrate westward. We now know that a sanctuary of the Persian god Mithras existed in a town in middle Egypt in the third century B.C. Although Greek cults were carried throughout western Asia along with the Greek colonists, the Greeks were more prone to accept the oriental worships than to impose their own. In 256 B.C. in Egypt the entire Greek retinue of the treasurer-general Apollonius, himself a Greek, ceased work at the time of the celebration of the purely Egyptian festival of Osiris-Isis. The final result of this process is to be seen in the first two centuries of the Roman Empire when the Egyptian Isis and the Persian Mithras worships were dominant religions in the Roman world. The methods by which they were spread can no longer be followed in detail; but suggestions of the organized propaganda which brought it about have appeared. A list has been found in Egypt, compiled apparently in the first century after Christ and kept in some Isis temple, in which the countries and cities are named where Isis cults then existed. The list includes India, Babylon, the Aegean islands and Italy.

Despite its formal continuance as expressed in temple building, festivals and sacred processions, the complete inadequacy of the Greek

city-state religions to satisfy the religious needs of the Hellenistic age is everywhere apparent. Nowhere is their complete lack of a spiritual content adequate to meet the new religious demands more clearly seen than in a book of Euhemerus of Messana, called *The Sacred Writ*, which appeared about 280 B.C. Euhemerus expressed his views on the rise of religions in a genetic-sociological study presented in the popular form which the utopias of the fourth century had taken. He asserted that he had been cast out upon an island located in the Arabian Sea, and had found there an inscription which recorded the names and deeds of the rulers of old who, by virtue of their activities for the welfare of mankind, had been deified and were now worshiped as gods. The origin of the gods was therefore explained in pragmatic-historical fashion as lying in the self-deification of mortal rulers or their apotheosis by a grateful posterity. The deification of the dead Alexander had obviously given a background of actuality for this theory. As proof of the Greek interest in sociological problems it may be noted that Euhemerus in his *Sacred Writ* found occasion to give a survey of the cultural development of mankind. In agreement with sophistical teaching he believed that mankind had slowly progressed through the civilizing activities of the oldest kings, of whom Zeus was the greatest, out of a primitive stage of unorganized living to the ethical and cultural conditions of the civilized life of his own day. *The Sacred Writ* of Euhemerus had little effect upon religious or philosophic thought in the third century B.C.; but in the second century it was widely read in Roman circles merely as a charming literary production attractive to the religious skepticism which was permeating the Hellenized circles of Rome.

Arising as a political expedient with a Greek background, divine worship of the living ruler found in Egypt a fertile soil for its further development. Ptolemy II Philadelphus was the first of the Hellenistic rulers after Alexander who dared to establish a cult of himself as a living god. In its Hellenistic practise the custom implied no belief in the divinity of the person worshiped, on the part of either the worshiper or the recipient of worship. It was an expression of loyalty to the ruler. In this form and with this meaning the Greek cities established cults to their Roman conquerors in the first century B.C. Among the Romans who thus received divine honors were Sulla, Lucullus and Cicero,

who was amused by it. Formulated by the founder of the empire and given a definite place in his new state organization, this practise of ruler worship, in the cult of *Roma et Augustus*, had far reaching effects in the Roman imperial period, particularly on the official relations of the Roman Empire with the Christian converts. The Christianized Roman Empire of the fourth century was forced to reject it; but in the weakened form of the political theory of the kingship by divine right it gave powerful support to the theory of monarchic sovereignty throughout the Middle Ages.

When the Greeks came into intimate contact with the many peoples of the old Persian Empire, the Greek conviction of the natural superiority of Hellene over non-Greek necessarily broke down. Intermarriage with native women must have done much in this direction. Through such contacts, indefinitely multiplied, there came to the Greeks an appreciation of the long established civilizations of the peoples among whom they lived. Berossus, a Babylonian priest of Bel, dedicated to Antiochus I a history of Babylonia which he had written in Greek. Manetho, an Egyptian priest living under the first Ptolemy, opened to the Greeks the knowledge of Egyptian history, which he chronicled in the Greek language. By these means and, more subtly and firmly, through the thousand minor pressures of daily intercourse, the new age developed a broader conception of humanity than that contained in the old antithesis of "Hellene" and "barbarian." The passing of *polis* patriotism displays itself in many and divergent forms—in the willingness with which Greek mercenary troops changed after a losing battle into the service of the victor; in the confidence with which the new master hired them; in the stoic teaching of the basic brotherhood of all men, of whatever racial stock; in the non-local character of the scientific spirit of the time. Eratosthenes of Cyrene, eminent geographer and librarian at Alexandria in the last half of the third century, expressed these new relations in his statement that men were to be differentiated no longer as Hellenes and barbarians but according to their excellent or their bad qualities. The Aristotelian view of the inborn superiority of Hellene over non-Hellene had broken down for intellectuals like Eratosthenes. But the new classification, by criteria of intelligence and character, did not find a like acceptance among the masses of the people dominated by Macedonian dynasties and by

Hellenic culture. Native reactions against the rulers and their policies, which bear many resemblances to modern nationalism, shook Egypt as well as Palestine in the second century B.C.

The view that the differentiation between Hellene and barbarian was no longer valid was generally characteristic of the time. Its philosophic formulation is to be ascribed to stoicism. This school was founded at Athens in 301 B.C. by Zeno, whose native city was Citium in Cyprus. Despite his Greek name his place of birth implies that he was a Semite, probably a Phoenician. If this be true, the fact that a Semite could establish a school in Athens, the center of Greek philosophic studies, gives early evidence of the denationalizing of "Hellenic" culture after Alexander's conquests had brought Greek and "barbarian" together. The political theory of the early stoic school agreed with the Aristotelian in the belief that man was a social animal and that his activity must be directed to the betterment of the social group to which he belonged. But stoicism abandoned completely the city-state, springing from it to the concept of a world-state in which all men were fellow citizens. "We do not dwell in separate cities or demes, each group bounded off by its own rules of justice; but we consider that all men are fellow demesmen and fellow citizens, and that life is one and the universe one" (von Arnim, *Stoicorum veterum frag.* I no. 262). To Zeno the reformed *polis* of Plato was "laughable." With the few fragments of the *Polity* of Zeno which have come down to us it is scarcely possible to offer more than conjectures as to its relation to the actual Greco-Persian Empire. No doubt the reality of Alexander's great empire, brief as its unity was, had inspired the idea of a single state which would embrace in a comprehensive citizenship the entire world penetrated by Greek culture. Zeno could not have regarded it otherwise than as a utopia, unrealizable but corresponding to justice based upon reason (*logos*), and to the divine law of brotherhood implanted in the heart of every person. The stoic world-state, therefore, in its broadly conceived and idealistic formulation, cannot be treated as political theory. Both the continuance of the city-state and the exploitation of the subject peoples by their Macedonian monarchs weakened the conclusions which must logically have been drawn from the original stoic ideal of cosmopolitanism and brotherhood. These logical conclusions the stoic did not insist upon. Soon,

in fact, stoicism compromised its teachings with the monarchic principle, so that the stoic believer could accept political preferment, even under absolute monarchs, if by his service he could feel conscious that he, individually, was working toward ethical ends and the good of mankind. By virtue of this compromise of its principles stoicism became an active force in the politics of the Hellenistic world. Antigonos Gonates, who in 277 B.C. established the new dynasty of the Antigonids ruling Macedon, was a stoic by training under Menedemus of Eretria and by friendship and admiration for Zeno. He played the game of politics as the exigencies of his situation as ruler of Macedon required. On the whole his political methods and the conduct of his task reflect credit upon the religious-ethical system in which he believed and upon his spiritual adviser Persaeus the stoic. In his attempt in the latter half of the third century to revive the old communism of the Spartan state by cancellation of debts and nationalization and distribution of the land, Cleomenes of Sparta was advised by the stoic Sphaerus. It is in the first two centuries of the Roman Empire, however, that the spirit of stoicism attained its maximum of practical value. Having adopted the monarchic principle, with the constant hope that the monarch might be permeated by the spirit of devotion to his task as a social duty, it became a guiding force among the higher classes who ruled the Roman Empire. In the person of the Emperor Marcus Aurelius the stoic devotion to that duty which a chance position in life might impose, reached its highest expression.

In its statement of the equality of Greek and barbarian and of man and woman, stoicism echoed thoughts which harmonized with two social tendencies prevailing at the time of its origin and throughout the Hellenistic period. The logical consequences of the stoic doctrine of the equality of slave and free man were not realized in antiquity in attempts to discard slavery as an economic and social system. It had its influence, however, in the time of the Roman Empire in shaping the public attitude toward slavery; and it may have influenced imperial legislation which afforded greater protection for slaves and materially lessened the former harshness of the Roman treatment of them. As to the new position of women which stoicism reflected, it may be that this represented a general revival in the Greek world of

the older Homeric Greek social ideal which had survived in the more primitive life of Macedon. A close intellectual bond existed between Alexander and his imperious mother Olympias of Epirus. Traces remain of his constant correspondence with her; and after his death she obtained a position of political influence such as no woman had previously held in the Greek world. During the following three centuries the Macedonian dynasties of the Ptolemies in Egypt and the Seleucids in western Asia produced numerous women of striking ability. Their power in politics is expressed in the names given to many of the Greek city foundations. The Seleucid cities Apamea, Nicaea, Laodicea, and the Ptolemaic towns Berenice and Arsinoë, are named after women of the Macedonian dynastic families. Arsinoë, the sister of the second Ptolemy and his wife from 273 to 270 B.C., was deified after her death, and an official worship of the two as "the brother-sister gods" was founded throughout Egypt. The images of the Ptolemaic and Seleucid queens appear on the royal coinage beside those of their husbands. So also the head of Cleopatra, the last of the Ptolemies, appeared on her coinage beside that of her Roman husband Marcus Antonius. Even under Augustus Caesar the heads of the feminine members of the Roman imperial family began to appear on the coins from the mints of Rome. In this practise, which is distinctly non-Roman, the imitation of the Hellenistic coinage practise is symbolic of the adoption of a greater freedom of action by women during the Roman Empire and the acceptance of the Hellenistic attitude toward them by society at large. The change in the position of women in the Hellenistic age was not confined to the teaching of stoicism and the political influence of the ruling classes. Women appeared among the Hellenistic poets and painters. A young woman, for example, was numbered among the students of the founder of Epicureanism. The Hellenistic city-states, in taking over endowments for the education of freeborn children, included the education of girls, establishing "supervisors of women" who appear in a number of official city documents which have come down to us.

The greater freedom of women evidenced in Hellenistic social life is connected with the higher value which that age accorded, in general, to the individual. This may be seen in the stoic teaching of the maintenance of man's spiritual freedom and his superiority to pain and

degradation through his will. It is also seen in the teachings and actions of the wandering preachers of cynicism. With them the cult of freedom of individual action and of disregard for all social conventions sometimes went so far as to take the form of vulgar indecencies. In the Epicurean theory, corresponding to its completely materialistic view of the universe, the state was regarded merely as a useful invention, a thing established by chance, by force or by contract in the interests of public security. The criterion of personal happiness was therefore dominant in their teaching. This new emphasis upon the individual corresponded to actual conditions of the century which followed Alexander's death. The first fifty years were a time of meteoric careers characterized by the sudden emergence and disappearance of powerful single personalities. The worship of the Hellenistic kings as "gods manifest" was a characteristic of the new individualism. So also was the rise of biographical literature and the belief of Polybius, the outstanding historian of the second century B.C., that the great personality is the determining force in history.

It may be that the increase in consciousness of the worth of the individual, which is notable in the Hellenistic period, was a psychological compensation for the loss to the Greeks of their *polis* patriotism and of that feeling of importance which political activity in the old city-state had given them. There was room enough in the service of the great Hellenistic monarchs for the abilities of ambitious and able men in every line of work. There was a constant market for Macedonians and Greeks as mercenary soldiers in the many wars and in the standing armies of the Hellenistic rulers. Throughout the third century the higher offices in the tremendous bureaucratic service of the Ptolemies were completely filled by them. The pay was good and opportunity for self-advancement of the individual was great. But the old loyalty to the citizen group and the feeling of participation, as decisive and free agents, in the activities of the state, were gone. The compensatory theory may also help to explain another phenomenon markedly characteristic of the Hellenistic age. This is the appearance of a tremendous number of private associations and clubs which were entirely non-political, and professional only in the sense that those engaged in one *technē*, soldiers, artists or poets, tended to group together. They exemplified the cosmopolitan spirit of the time in that membership was not

confined to Greeks alone. A recent bit of information from the time of Augustus Caesar is highly characteristic, namely that a club for women existed in the Egyptian capital Alexandria.

The Hellenistic civilization of the three centuries preceding the founding of the Roman Empire must be approached as a composite of many types of local hybrid cultures: Greco-Egyptian, Greco-Asiatic (which must be subdivided into numerous forms such as Greco-Syrian, Greco-Bactrian, Greco-Asia Minor, etc.), Greco-Italian. The penetrating and dynamic agencies on the whole were Greek; but the degree of the Greek penetration necessarily varied in each country and between the urban and rural districts of each locality. In the urban centers, where the Greeks congregated in large numbers, the Hellenic externals of life, as represented by temples, gymnasia and the adoption of the Greek style of dress, were marked. In the rural districts even these external Greek manifestations would decrease in number and variety, probably to the vanishing point in the countryside which was far removed from the great lanes of travel. Official use of the Greek language in all of the Hellenistic kingdoms made a speaking and reading knowledge of Greek a necessity for every man of culture and of official position. It is clear that the amount of literacy was greater in the oriental states after they had been taken over by the Greeks than it had been previously. The upper and middle classes could read and write Greek. The lower classes made use of professional scribes for their letter writing and for the preparation of their contracts and petitions to be handed in to the government officials. The knowledge of writing in the old scripts, the Babylonian cuneiform and the hieroglyphic and demotic scripts in Egypt, was beginning to disappear after 200 B.C. In a fragmentary letter of the second century B.C. a mother writes to her son, both being "culture Greeks" and possibly Greeks by race, that she is glad to hear that he is learning the Egyptian letters and is to teach Greek to the children of an Egyptian physician and thereby earn his living. In the time of the Roman Empire the knowledge of the old Egyptian hieroglyphs was retained only by the priests of the old Pharaonic religion. There, too, it disappeared completely in the second century A.D. When the Egyptian language was taken up again and used as a literary form in the Christian propaganda in Egypt, the alpha-

betic symbols used for the writing of Coptic Egyptian were largely taken over from the Greek.

In the great Hellenistic monarchies of Egypt and Syria general education still remained a matter of private initiative, without state support. In the city-states of the Greek peninsula and of Asia Minor it became customary for wealthy men or the monarchs of the time to grant endowments for the education of the freeborn children of a city. In such cases the city governments necessarily took over the problem of investment and management of the fund, appointment of teachers, methods of testing or examination of the pupils, and the subjects to be taught; but the cities made no grants in aid out of the city taxation. The mental disciplines were the old ones—writing, reading and literature. To these were added harp and lyre playing and musical theory, with a rather disproportionate emphasis upon physical education as represented by semi-military exercises such as javelin throwing. The further training of young men in the Hellenistic period was under a system called the ephebate. In the late fourth century in Athens the sons of citizens in their nineteenth and twentieth years, called ephebi, had been given a probationary training for military service under the direction of state officials. The system was widely adopted by the free Greek cities and in the great monarchies of the Hellenistic period. We have no proof of state support for the ephebe system. For Ptolemaic Egypt one certain instance of its support through private endowment is known from a contemporaneous document. It centered about the gymnasia of the cities and seems to have retained some connection, along with the gymnasia themselves, with the right to qualify its members for military service. That it was open only to the class of "Hellenes," which no longer denoted Hellenic blood, is certainly established for Ptolemaic Egypt. Inclusion among the ephebi was a mark of social distinction. In Egypt the ex-ephebe was freed from the poll tax paid by all the Egyptian lower classes, and he was set apart as a member of a social aristocracy. The class cleavages of Hellenistic society were therefore no longer those of native-born and alien. The new classifications were economic and cultural—those of poverty and wealth, participation in Hellenic culture and the lack of it, or the standing which one might have attained in the service of the autocratic monarchies.

For the progress of Greek higher studies, particularly in the fields of Greek literature, linguistics, medicine and geography, the museum at Alexandria was an organization of outstanding importance. Founded by Ptolemy I and directly modeled in its organization upon the philosophic schools at Athens, it differed from them in being primarily a place of research rather than a school for instruction. Under support from the Egyptian state, scholars and literary men carried on their work there. The library established in connection with the museum was the first attempt that had been made on a large scale to assemble the complete output of Greek scientific and literary activity. The idea certainly came from the modest collections of rolls which had been made at the philosophic schools at Athens. About 240 B.C. 490,000 rolls were said to be in the Alexandrine library. How many volumes this would represent in the modern sense cannot be estimated, because we have no knowledge of the number of duplicates which were included. It is known that the first three Ptolemies went to great trouble to procure copies of all available books written in the Greek language. A library was established at Antioch by the Seleucids and one at Pergamum by the Attalid rulers of Asia Minor. The directors of the Alexandrine library in the third and early second centuries B.C. were distinguished literary or scientific figures in the world of the time. Zenodotus of Ephesus, the great Homeric critic, was the first librarian. The poet Callimachus of Cyrene was active in the cataloguing of the rolls. Toward the end of the third century B.C. Eratosthenes of Cyrene, an outstanding figure in the science of geography, was followed as librarian by Aristophanes of Byzantium, another Homeric scholar.

The importance of the Alexandrine museum and the libraries mentioned above as recognized and continuing centers of higher studies, with collections of materials available for the use of scholars, must have been great. Unfortunately we do not know what conditions were imposed upon the use of the books, nor can we prove to what extent they were used. Under the government monopoly, established by the Ptolemies, of the manufacture of paper out of the papyrus stalk, the increase in the output of paper must have been enormous. The process had been known and used by the Pharaohs from the beginning of the third millennium B.C.; and the use of papyrus for books and accounts was

customary in Athens in the fifth century. But it was in the third century B.C. that papyrus assumed its position as the common writing material of the Hellenistic world. This position it held until the eighth century after Christ. The actual connection of the increase in paper manufacture with the enormous increase in the number of authors and books which marks the Hellenistic age cannot be established in detail because of our lack of the necessary data; but it seems to be obvious that the increased manufacture and use of papyrus sheets for writing was both a sign of the rise in the general level of culture and an agency which helps to explain the increased facility of literary expression.

As soon as Alexander had crossed into Asia Minor to carry on the war against Persia, and had begun to free the Greek city-states of the Aegean coast from Persian rule, one problem of immense administrative and economic importance immediately confronted him. This concerned the system of agricultural landholding of the Persian Empire. According to the system which the Persian kings had inherited from their predecessors in western Asia and in Egypt, much of the arable land was royal domain. Other great stretches were in the possession of the temple organizations. Both of these types of holdings were worked by the peasants of the kings or of the temples, living in villages which were the chief administrative units for the payment of their crop rents and their sundry taxes. To these villages and to their task as king's cultivators or cultivators for the god of the temple, the peasants were bound, their names appearing on the royal records with their village connection. In certain parts of Asia Minor, where Persian overlords had been assigned large domains, the system had taken on a semi-feudal character. Alexander wisely decided that he could not disturb this tremendous administrative machine which had functioned so long. An official letter which he wrote in 334 B.C. to the small Greek city of Priene has come down to us in a copy inscribed upon stone. In the letter he announced his decision that the city should be autonomous and free, owning its own land, both the city real estate and the farms of its citizens. "The countryside I recognize as mine, and that they who dwell in villages there are to pay the rentals." In other words, the royal domain and the peasants of the king were to retain their old status. In Egypt, which Alexander conquered

in 332 B.C., similar great complexes of royal and temple domains existed; and his decision there was necessarily the same.

The idea of ownership of land by the state and its cultivation under a system of helotage, as in Sparta and Thessaly, and that of the large estate system owned by nobles and worked by renters, as in Macedon, were familiar to the Greeks. The dominant system of the city-states, however, had been one of free private land-holding. In this most fundamental and important economic feature the background of the new Hellenistic society differed, therefore, from that of the city-state. No single pattern can be constructed, no one formula enunciated, which will adequately cover the vicissitudes of the royal domain system in the Hellenistic monarchies. In western Asia the Seleucids adopted toward their domain a free policy of alienating it to members of the royal household or to important individuals whose support they required. Sometimes the lands thus alienated were held as revocable grants, sometimes sold outright. The Seleucids disposed also of large stretches to the new city-states as the essential agricultural hinterland of their city foundations. There are indications that it was a recognized method, employed by important Greeks in the troubled period of the forty years immediately following the death of Alexander, to obtain grants of land, mortgage these to a temple for what ready cash they would bring, and allow the mortgage to be foreclosed by the temple treasurers. In this and in other ways the land complexes held by the temples, especially in Asia Minor, became very large. As a rule, however, the requirement was made that land alienated from the royal domains to individuals must be enrolled upon the land register of some city for taxation and record purposes.

The entire political situation of the Ptolemies in Egypt was different from that of the Seleucids. Egypt was a compact unit geographically; and it offered the possibility of complete control by the rulers such as was out of the question in the widespread, loosely knit empire of the Seleucids. Hence we find an economic absolutism established over almost all phases of production in Egypt such as could be attained nowhere else in the world of the time. According to the Pharaonic tradition, firmly rooted in a practise of hundreds of years in Egypt, the arable land belonged to the god-king, not to the peasants who worked it. The Ptolemies had no reason to break with this tradition. They

accepted it, emphasizing in every possible way the theory of their ownership, particularly as against the lands cultivated by the temples. Most of the king's land was held by the Egyptian population as crown renters (royal peasants) under direct lease with the king. A lesser amount was given out to the Greeks, Macedonians and other aliens who formed the mercenary armies of the Ptolemies, to be held and cultivated by them so long as their active service under the king continued. Land reclaimed under the skilful Greek irrigation engineering of the time was given out, under Ptolemy Philadelphus, in immense tracts to wealthy and energetic men for development, this "gift land" being revocable at the king's will. The status and management of one such great tract, comprising 6250 acres situated in the Egyptian oasis called the Fayum, is now known to us in intimate detail. The rents which the Ptolemies derived in wheat and barley from the royal domains, under whatever classification these might be held, made the royal household of Egypt by far the greatest grain merchant of the Hellenistic world.

The same system of domains owned by the king was widespread also in the Pergamene kingdom of western Asia Minor. Inside the limited boundaries of the old Macedonian kingdom private ownership continued to be the dominating system, the peasants owning in fee simple, for the most part, the lands which they tilled. But in the lands of the Balkans outside of Macedon proper which were brought under Macedonian control by the Antigonids, the theory was widely applied that the state, i.e. the king, owned the land. The royal domain system, therefore, was widespread in the ancient Near East when the Roman Republic extended its control into that region in the second and first centuries B.C. Technically these lands became the public domain (*ager publicus*) of the Roman state. In 30 B.C. Cleopatra, the last of the Macedonian Ptolemies to rule Egypt, had failed in her ambitious effort to reestablish Egypt as a great imperial power through the help of Marcus Antonius. The problem of the royal domains of Egypt then faced her conqueror Augustus Caesar, as it had faced Alexander the Great three hundred years earlier. Augustus' solution was that he, as representing in his magisterial position the Roman state, should keep the control of Egypt in his own hands and with it the control of the royal domains. With that decision the problem of the state as great landowner and agricultural pro-

ducer in the lands bordering upon the eastern Mediterranean was shifted to the shoulders of the Roman emperors and their administrative advisers.

The Roman World

I. ORIGINS AND EXPANSION. During the second millennium before our era several successive waves of migrants invaded Italy from the Danube and Swiss valleys. These immigrants before 1000 B.C. drove off most of the sparsely settled non-agrarian savages from the arable lands of north and central Italy. The invaders brought with them bronze implements and weapons, employed domesticated animals, cultivated cereals and were beginning to acquire a knowledge of grape culture. In historical times they are found speaking dialects of a common Italic language with a conservatism that seems to imply the absence of extensive race mixing. Apparently they had come in compact hordes, had seized and settled the land, and made it possible to preserve a fairly uniform culture through the larger part of the peninsula.

The new settlers took possession of the Roman and Latian plains about 1000 B.C., at a time when iron was beginning to displace bronze for weapons in Italy. The Latins settled in villages on defensible hills that had springs of water, and apparently divided the lands about the villages into individual lots for cultivation. In historical times (and probably this was an early institution) they usually set apart a portion of the land for public use, and hillsides unfit for cultivation were kept as common grazing grounds. The institution of private property in land seems to have been very old among these people, but details for the early period are lacking; we know only that as early as 450 B.C. the twelve tables recognized an owner's complete testamentary powers as regards his property.

Of the government before the regal period we can learn very little. Apparently, to judge from survivals, the villages annually elected praetors (foremen) and aediles (temple keepers) in town meetings. The communities that made up the Latin tribe also had an annual festival of the tribe and at this festival elected a tribal praetor who could summon and lead the tribal forces in time of danger. Since the Latins had better lands than the mountain folk on the east and south, common defense was probably very important. The old Roman fetial institution reflects the fact that

the plain-lands of Latium were subject to invasions, for the fetial law concerned itself entirely with wars of defense and the procedure of demanding restitution.

When the neighboring regions were settled and raids became frequent, many of the lower village sites were abandoned and the villagers migrated to the stronger communities. Thus, because of danger near by, some seven or eight cities grew up in Latium in place of the many villages. Thus originated the city-state in Latium. The farmers thereafter had farther to go to reach their plots of land each morning, but their families were at least safe in walled towns.

With this important social change—which seems to belong to the ninth, eighth and seventh centuries in Latium and Tuscany—the form of government changed here and there. Some of the Latin cities simply developed the old town meeting and continued to elect annual praetors. In Rome, however, which because of its favorable position received a particularly large accretion of settlers, three villages united in a common government within an extensive earthen rampart. And since one village at least consisted of a non-Latin group, it is likely that a firmer government was needed at Rome than in some of the other Latin towns. Here the town meeting (*comitia curiata*) consisted of three times the ordinary ten curiae, and the elders were organized into a council (the senate) to give advice to the magistrates. Finally, probably during the seventh century, a chieftain (*rex*), holding office for life, was substituted for the annual magistrates. Since the legends regarding the kings are unreliable, we do not know whether this change came by usurpation or rather by choice of the people at some time of great danger. As only the names of the last kings, the Tarquins, are certainly Etruscan, the change seems to have taken place before the Etruscan conquest of Latium in the sixth century. Tradition was very firm in the belief that the advisory council of elders existed through the regal period and that the people elected the kings. What the principle of organization of the town meeting of the thirty curiae may have been we do not know. Clan feeling was

very strong at Rome, as is shown by the late survival of *talio*, and tradition held that the heads of families made up the assembly; but that does not prove that it was organized according to *gentes* (clans). The word *curia*—derived from *con* + *vir* (meeting of men)—is quite non-committal. At any rate, during the regal period this assembly lost much of its importance, for when the republic was restored a new assembly by hundreds (*comitia centuriata*), consisting of property-holding men of military age, constituted the town meeting. This is apparently a military assembly that had grown up during the period of warfare inaugurated by the Etruscan usurpers.

During the later regal period, at least, Etruscan princes were autocrats in Rome. About 500 B.C., however, these foreigners were expelled by a revolution, and the old republican form of government was restored. This new republic of Rome attempted (as we learn from the first Punic treaty) to control the whole of Latium, but the treaty of the Latin league, signed a decade or so later, shows that it failed in this attempt. Rome had to be satisfied with less than half of Latium and with a treaty that recognized the equal status of the other Latin cities. However, Rome's leadership was recognized in time of danger, and it became the dominant city in a league which after some time was strong enough to repel all attacks.

The government of the city was now of the old Italic type with a few modifications. The men capable of bearing arms constituted the primary assembly, but since the wealthier, who could provide good armor and horses, had to bear the brunt of the fighting, these were also given the weight of influence in the assembly. That is to say, while the people were divided into five classes according to property, the votes accorded each class were so weighted that the centuries of the first class together with the horsemen controlled the assembly. This assembly elected the magistrates and also made all important decisions. The two annually elected consuls were the executive magistrates. They had at their service for advice a senate of about a hundred nobles, normally including the ex-magistrates.

Under the last of the kings Rome had grown to be one of the largest cities west of the Adriatic Sea. But with the severance of Etruscan connections, the banishment of the court, the loss of Latian subjects and the lapse of building operations and of commercial enterprise, Rome fell into a long decline, during which the mountain-

eers raided far into her territories. After a century of hazardous experience, however, Rome at the head of the league slowly began to make territorial advances into Etruria and then against the Samnites. Rome now formed a new and larger federation on lines that seem to have been novel in the ancient world, a federation whose strong support is largely accountable for Rome's unusual success. There are two simple but important principles apparent in this federation: one, that in all compacts signed by it Rome was to retain controlling power in any common action; the other, that the members of the federation were not to be affronted by the exaction of a tribute or by any other visible sign of inferiority. Colonization was carried on by the federation as a whole; the newer *municipalities* were incorporated in the Roman city-state with local autonomy and yet with full participation in the Roman assembly; municipalities farther away, not yet ready for such participation, were placed in a probationary stage with half-citizenship; while the outer circle of cities or tribes was given defensive alliances which provided the protective power of the whole federation in their defense. This was a federation based upon an intelligent self-interest seasoned by a comprehension of partners' interests that in time made Rome very strong.

However, the result of the expansion of the federation was of course that its frontiers abutted on a very large number of barbaric tribes; so that quarrels were apt to arise on some border at any time, and the temptation to use the great force put at its disposal for the advantageous adjustment of such disputes was naturally irresistible. As a result its forces were usually engaged in warfare at some point or other, and before the federation had been in operation for a century it had absorbed the whole of Italy from the Arno to the heel of the peninsula, and the Roman city-state, which was still a small fraction of the whole, was the controlling element throughout. It is a curious fact that this period of rapid expansion was precisely the period during which the plebeian element gained the right to hold magistracies and to organize a new legislative assembly based not upon wealth but upon local groupings where the principle of equal manhood suffrage was recognized. It was in a period of popular sovereignty that the city-state of Rome made its most daring ventures in territorial expansion.

Rome's arrival in the south brought her into contact with new neighbors who soon presented

her with a set of tangled problems. Whatever the underlying forces were that impelled Rome and Carthage to clash, it is clear that Rome found it difficult to avoid the logic of the situation in which she was placed. When, at the request of Messana, she entered the First Punic War, it was evidently to protect from the encroachments of Carthage a city (Messana) that had appealed for admission to Rome's league. An important factor in the beginning of the Second Punic War seems to have been the plea of Marseilles, Rome's close friend and the commercial rival of Carthage. At the end of one war the senate was induced by a war-incurred debt to abandon the ancestral policy of exempting new acquisitions from tribute, and made of the cities of Punic Sicily not allies and "equals" but tribute-paying subjects that had to be held by a standing army against revolt and invasion. At the end of the second war Spain, which had been occupied for strategic reasons, was reduced to the same status. Rome was now an imperial democracy. The success in these wars had changed the very nature of the Roman constitution.

Rome's expansion eastward was in many ways even less fortunate. Her intervention in the affairs of the Greek states was an ill managed experiment in sentimental politics. It cost her both trouble and prestige, and led through a series of bickerings, treaties and revolts to the destruction of Corinth and the reduction of Macedonia to the status of a province. This experience was followed by a period of caution, during which expansion was out of favor. But with Pompey expansion of a new kind began (67 B.C.). The Gracchan system of tax gathering had raised up a strong group of capitalists who profited from public contracts. When the revenues of Asia were menaced by the raids of Mithridates, these capitalists advocated the pacification of the Orient and the inclusion into Roman provinces of as large a part as possible. This financial power found a sympathetic agent in Pompey, who was sent east ostensibly to check the invaders but actually to pacify the oriental world and lay it open to the financial operations emanating from Rome. He did his work thoroughly. The contract system of tax gathering was extended—although in a milder form—over all the Asiatic provinces, so that the revenues of the state were nearly doubled and the operations of the capitalists enormously increased.

Caesar's invasion of Gaul (58 B.C.), on the other hand, was a simple act of military aggres-

sion, instigated by personal motives rather than by the desires of a class or by large considerations of state. His plans and preparations show that he was primarily bent on raising an army with which to make himself the most powerful man at Rome. Thus the inclusion of the last great province was in a measure an accident. However, with Caesar we reach virtually the end of territorial expansion. Since there were no longer any strong powers to fear, nor the need of winning distinction and prestige through military achievement, the emperors could safely limit themselves to finding and adhering to sound frontiers. Such frontiers were established by Augustus and were in general accepted by his successors.

The conquest and organization of a vast empire by a city-state was a unique event in history. The secret of success seems to have been the capacity to form and control an expanding federation of autonomous peoples while the whole of Italy was being secured. Eventually, when success had blinded the senate to ancestral methods and many of the nobles had fallen into the temptation of political exploitation, the state could nevertheless continue to expand successfully because of the momentum won by the sacrifices of the fourth and third centuries.

II. SOCIETY AND ECONOMIC CONDITIONS: THE REPUBLIC. The republic was founded and organized by "patrician" landholders who considered themselves superior to the common folk by reason of their descent. At the time they alone could hold magistracies and priesthoods and they alone had a vote in the senate on the most vital matters. This does not necessarily mean that they owned large estates. Many seem to have been active farmers and, with the intensive hoe culture of the day, a man could hardly till more than ten acres of land. Legend, at least, insists that some of the old consuls, like Cincinnatus and Curius, worked their own lands. When the plots were larger, we must assume that they employed renters, free laborers and to some extent slaves.

The "plebeians," who could vote but could not at first hold office, were apparently numerous. The origin of the class is obscure. It is usually assumed that they were Latins who had in the course of time lost their farms by ordinary economic processes and had, especially during the Etruscan occupation, become laborers and artisans and dependent renters. It may also be that some of them were liberated serfs. There is

no support for the old-time hypothesis that they belonged to a conquered race.

Since Rome's power and resources dwindled after the restoration of the republic, and commerce and the crafts declined, there was much economic distress during the fifth century. And since custom permitted enslavement for debt, and the patrician possessors were not inclined to give relief, there was a steady demand on the part of the plebeians for political recognition whereby they might improve their condition. Not much progress was made until after Veii was captured in 392 and a large part of its land distributed to Romans. The humbler citizens apparently received these allotments, for we learn that four new country *tribus* were then made. This increase in the number of property-holding plebeians apparently gave them the prestige that enabled them gradually to win complete equality with the patricians. Thereafter the term patrician represented only a hereditary distinction of no great significance, for in the third century a new social *nobilitas* of more practical value in politics grew up, a nobility of families, whether of patrician or plebeian origin, descended from anyone who had ever held the consulship.

From the capture of Veii (392) to the First Punic War (264) the aspect of Roman society did not greatly change. Agriculture continued to be the chief industry. There was relatively little maritime trade, if we may judge from the evidence that archaeology has left. Rome developed no distinctive craftsmanship, though here and there nearby towns like Palestrina made their mark in fine metal work. However, a fairly large artisan class grew up for the supplying of ordinary household ware, farm implements, arms and armor. And the activity of Appius Claudius in his censorship (312 B.C.)—building an aqueduct for the poorer district of the city and enrolling the urban poor in whatever ward they might select—indicates that the free urban proletariat was strong enough to demand attention. But in general the outstanding fact of this period is that a gradual colonization of lands taken in wars kept Roman society directed landward, and society on the whole remained of the type associated with the name of Cincinnatus. It was a society such as Thomas Jefferson considered the ideal for his day.

During the first period of foreign wars (First Punic War, 264–241; Second, 218–202) there was again no great change at Rome except that in assuming direction of these critical conflicts

the senate grew in importance and prestige, and the senatorial nobility came more and more to stand apart in the esteem of the commons. It is in this period that the new aristocracy, by sheer accomplishment in an epoch of very great danger, established the tacit custom that, except in very unusual cases, only the political nobility was to be trusted with high office.

The spread of the plantation system as a result of the Second Punic War led gradually to a very great social change. During the war small farmers had been cut down mercilessly in battle, so that much land was on the market and more fortunate survivors could expand their estates. Moreover, as a result of the devastation caused in southern Italy and in the Po valley, the state expropriated extensive areas. Only a part of these could be colonized at once; naturally the northern portion, which was in danger of being reoccupied by the Celts, was settled first. It was usually settled in moderate-sized lots. In order to make the southern lands productive to some extent at least, they were rented out in large tracts at low rentals to those who would take them. The senators, who made this provision, were largely the ones who took the leases. The lands went into grazing and to some extent into wine and olive raising and, since free labor was scarce, the landlords purchased war captives and Greek slaves for the development of their ranches and plantations. It is very likely that some of the expansion in Spain, in Liguria and in Epirus was pushed with greater vigor than political policy required simply because the generals in command were aware that Italy could absorb a large number of slaves. Thus during the period between Scipio and Tiberius Gracchus the aspect of Italy changed to a considerable extent. Plantations spread rapidly over the better lands, and in the south large ranches extended up into the hilly country. Small farmers were still quite numerous, however, especially in the foothills and mountain valleys of the central Apennines. During the first thirty years the agrarian youth—none too numerous—who found opportunities denied them at home took colonial plots in Cisalpine Gaul. When these plots gave out (about 170 B.C.) it became the custom to cross the Po and try one's fortune among the Celts of Lombardy.

Apparently there was still not much maritime commerce among the Romans. The Greeks of south Italy and the Greco-Oscan population of the bay of Naples were active on the sea, and some Roman funds seem to have found place-

ment in their enterprises, but not many. The inscriptions of Delos—which was the center of Mediterranean trade after the destruction of Corinth—give a clear picture of the commerce of this period. They reveal very few traders from Rome before the first century B.C., but very many from Asia, Syria, Alexandria, Greece, and not a few from the Greek cities of Italy that were allied to Rome and that profited by Rome's policy of requiring open ports for her allies. The fact seems to be that the opportunities in land exploitation opened by the Punic War and by the new system of farming with slaves attracted most of the Roman capital landward again. When Tiberius Gracchus—a young aristocrat who had read widely in stoic philosophy—reached the tribunate in 133 B.C., he observed that those parts of Italy which had formerly been occupied by numerous freeholders now chiefly supported slaves, and that because of the scarcity of free men of property Roman consuls had difficulty in making up their levies when a war broke out. He also remarked that many Romans had grown wealthy by illegally squatting on public lands or occupying the public lands which their fathers had enclosed, and that all this time an urban proletariat was growing up which found no way of making a living.

One might expect that, with the increase of wealth in the numerous large households and the herding of poor free labor to the city, some distinctive industry might have arisen at Rome as at Capua. But this did not occur. Indeed the artistic bronze and silver work for which the neighboring Praeneste had been known—and one of the finest pieces found bears the signature of a Roman—actually ceased to be made at this time. The explanation for this trend seems to be that, on the one hand, the recent campaigns in Greece and Asia had attracted attention to the beautiful wares and articles being wrought in the East, so that imports from there captured the best markets at home, and that, on the other, large households frequently had skilled slaves who supplied the rougher articles. Villa slaves certainly were trained as smiths, masons, carpenters, joiners, cobblers, makers of clothing and to some extent even as jewelers. It was also true that emancipation was very common at this time and that skilled slaves set free often became humble craftsmen who supplied articles of mediocre value in small individual shops. Conditions, in fact, were not at all favorable to the rise of an industry that could compete with those which had been established long ago in the more

advanced East and in the old Greek portion of Italy.

Roman society remained agrarian-military. The aristocracy, drawing its livelihood from slave labor on large estates, not infrequently from a general's share in booty, and occasionally from a shrewd marriage, and basing its claims for social distinction upon ancestry and political office, remained a close corporation of less than a hundred outstanding families living in one city. The men were generous in their devotion to political and military service, laboring incessantly—whether on foreign missions or arduous campaigns or conscientiously attending the sessions of the senate and the courts. For the most part they still revealed themselves as men of integrity in dealing with subject nations, and as men of puritanic instincts in their social relations at home. But they were also growing imperious toward provincials, harsh toward their "allies" in Italy, inconsiderate in their treatment of their slaves, and they were beginning to insist upon the preservation of the status quo and to interpret the political practises of their own day as unalterably final. A middle class still existed, to be sure, consisting of those landholders who had not broken into the ranks of the nobility, certain state contractors and a few men who had made some profit in money-lending and in commerce, but it was not strong enough to receive much attention from the ruling class. A lower class of poor farmers and shopkeepers also clung to the civilized fringe of society. Below were the large hordes of slaves, ready to do what old Romans considered "dirty work," but emerging by gradual emancipation into Rome's populace.

The Gracchans tried to alter this state of things by colonizing the urban poor on lots to be reclaimed from the squatters' estates, by organizing a strong middle class of *equites* who were to have the privilege of profiting from more state contracts and of being recognized in the panels of the law court, by encouraging Roman commerce in the colonies planted at Carthage and in south Italy, and finally by restoring some governmental responsibility to the tribal assembly and at the same time reducing the powers and pretensions of the senate and the aristocracy. The program was carried through, but received no fair trial because after the murder of Caius Gracchus no leader arose to direct its machinery. The middle class, however, became a power through the Gracchan reforms and frequently checked the aristocracy, but being built up on the privileges afforded by state contracts this

group became in time a menace to good government by leading the way in the exploitation of Rome's subjects. As we have noted above, it was these contractors who were largely accountable for the expansion of Rome through Asia and who used Pompey as their agent. The last half century of the republic was to no small extent a struggle between the senate and the equestrian order for an advantageous position from which to harvest the profits of imperialism.

By Cicero's day all Italians were citizens of Rome. The body politic then included not only the classes mentioned above but a much extended group of small farmers of the hill region, the merchants of the south and the industrialists of Capua, Tarentum, Puteoli, Arretium and other places. These new peoples, however, were too far away to be effective influences in the Roman primary assembly, and the men who controlled Roman politics were not so eager to give up their power as to substitute a representative assembly constituted from the whole of Italy for a docile primary gathering. Caesar, when he became dictator, was the first to recognize these new elements in the city-state, and in his colonization and in his economic program he considered the needs of merchants, artisans and manufacturers as well as of agrarians. His death, however, checked progress along these lines.

Indirectly Caesar's rejection of the tax-contract system instituted by Gracchus damaged Roman commerce severely. The publicans had gathered the tithes in kind and had been compelled to build up a shipping and distributing machinery to dispose profitably of the produce, and this had drawn them into trade. But Roman shipping was as coy as American shipping has recently been. When the immediate necessity vanished, the carrying trade fell away to the easterners who were more accustomed to it, and the Roman *negotiatores* then confined their activities to financing estates that were falling into Roman hands. In the early empire Rome was living not on commerce and industry but largely on returns from capital invested in Italian and provincial lands and mortgages.

III. LAW. Rome's foremost gift to civilization was a great digest of laws. That digest was made at the end of a thousand years of legislation, but even at the beginning the Romans seem to have revealed a striking respect for orderly procedure. Nowhere else can one point to a government resting upon a primary assembly which during several hundred years worked out a series of civil

revolutions by reasonable compromise and without bloodshed. We do not yet know enough about racial inheritance to explain such behavior. One may of course point to the influence of environment and recall that centuries of experience in defending fertile lowlands against hungry mountaineers would naturally breed respect for property rights; that early experience with world wide commerce in the days of Etruscan domination compelled the Romans to devise liberal forms of contract; that the traditions of individualism which long prohibited the formation of a strong central government elevated the patriarchs and the patriarchal family, which in turn encouraged the formation and safeguarding of estates, and that this evoked well considered laws of property and of inheritance; and finally that the long survival of an aristocracy insured continuity in legal conceptions. We may admit all this and still be compelled to assume that the ancestors of the early Latins who invaded Italy had already, by some hard process of environmental elimination of the discordant, coalesced into a racial group possessing fairly uniform physical and temperamental characteristics. Archaeology has shown that the invaders were land seekers who came and took their land in compact groups; and linguistics, by contrasting the conservatism of early Latin with the wreckage that occurred in the race mixtures of the early Middle Ages, supports the conclusion that the Latin groups long remained relatively homogeneous. It may well be that what we consider traits of Roman character were in large measure a common inheritance of the Italic peoples from prehistoric times.

In coming to a survey of Roman law it is not worth repeating what Roman antiquarians said of the putative laws that antedated the decemviral code. The evidence is too infirm. The fragments of the twelve tables, on the other hand, give a fairly reliable picture of the legal customs of the middle of the fifth century B.C. They are so thoroughly Roman in character that the old hypothesis of a possible borrowing from Greek need not detain us. This code contains a somewhat broad collection of civil, criminal and religious law. Some of the sentences on civil matters are more advanced than one would expect from a people in their state of culture. For instance, the formal mode of purchase in the presence of five witnesses applied only to land, slaves and cattle; all else could be sold by informal *traditio*; contracts, loans, mortgages and trusts were provided for by fictional forms of

sale, and in all these the rule applied that the spoken word (witnessed, of course) was valid. The law of the twelve tables did not spring out of the primitive rural economy imagined by Mommsen's day but out of the experience of the early commercial city which the spade has now disclosed to us. The fifth table seems to permit a father to leave his property by legacy outside of his family, a progressive measure which may have arisen in an aristocratic society eager to conserve estates in the hands of some responsible person who would thereby be able to meet the political obligations expected of landowners. On the other hand it is a mark of a strong democratic feeling that early law did not recognize primogeniture or distinction of sex in inheritance.

In criminal law we meet with a conservatism that is due to the lack of an executive machinery belonging to a strong central government, which in turn reflects the survival of patriarchal customs. For instance, theft, fraud and personal injuries were still left in the civil code for private initiative to deal with, and although retaliation was not recognized, the right of *talio* is kept as a factor of compulsion in order to force the culprit to submit to judgment. This is doubtless due to the very slow acceptance of administrative obligations on the part of the government and to the long survival of patriarchal customs. Peonage for unpaid debt was still permitted, but the assumption that the creditor could slay the debtor has been proved to rest upon a misinterpretation of the evidence. We also find that at Rome as elsewhere custom was slow to substitute civil procedure for what could be accomplished by religious awe. A sentence of the eighth table reads: "He who burns another's grain shall be under the curse of Ceres." That is, the culprit was outlawed. The state did not assume obligations where old religious traditions were still effective.

This codification of custom had a certain retardant effect in that it tended to stereotype procedure and precedent. However, in several instances where the publication of custom revealed incongruities with progressive experience, it helped to provoke criticism and thus promoted precision in legal thought. So, for instance, the prohibition of marriage between a patrician and a plebeian was presently corrected by statute. Similarly, in the next century, when the institution of coinage led to easy money, speculation and debts, the people passed a bankruptcy law which indirectly discouraged the enslavement for debts permitted by the code.

In 366 B.C. the consul was relieved of judicial duties, which were then assigned to a praetor. This new magistrate could give his whole attention to administering justice. He was not necessarily a legal specialist, but he was a senator and as such was supposed to be familiar with much of the law. The early praetors apparently won the confidence of the people by their judgments, for the primitive custom of according discretion to the judge was not later hampered by regulation. In fact the praetor's powers were tacitly permitted to grow and were actually enlarged by the Aebutian law until he assumed considerable liberty, by means of legal fictions, to interpret old laws in conformity with contemporary ideas. These interpretations would be recognized in formulae set forth in the annual praetorian edict, which came to be considered valid in law unless abrogated by statute. Thus Roman law was largely judge-made and was kept abreast of changing conditions.

In the third century (242 B.C.) a new court was instituted to pronounce judgment in cases arising between citizens and foreigners and also between two foreign litigants. This proved to be all-important in the development of Roman law. Since the civil law was applicable only to citizens, foreign trade would be discouraged unless non-Roman commercial practises were recognized as valid in the Forum. The institution of a court for foreigners was not a Roman invention, for several Greek trading cities, as well as Carthage, had the custom of keeping an official arbitrator at the harbor in order to settle disputes and thereby encourage trade. The institution, however, gained special importance at Rome because Rome's civil law could so readily absorb the liberal customs of the peregrine court, because Rome's stable government gave an unusually long term to such a process of absorption, and because Rome's management of her federation also assumed the necessity of equitable dealing with non-Romans.

It is a mistake then to suppose that respect for *aequitas* and *jus gentium* came in with stoicism in Cicero's age. To be sure, we find the phrase *jus gentium* first in Cicero, but we do not happen to have any pre-Ciceronian prose in which it could well occur. Since ninety-five percent of republican Latin has been lost to us, we dare never draw conclusions *ex silentio* regarding the dates of republican customs. In Cicero's day the phrase was well established with two distinct meanings, the one here referred to, in which *jus gentium* includes the accepted customs of civi-

ized peoples in commerce and communications, the other in which the term refers to the accepted practises of civilized peoples in wars. In the rules of warfare Rome showed a sensitiveness to foreign custom at least as early as four centuries before Cicero; in commercial practises it is probable that trade with Carthage and Sicilian Greeks created a recognition of *jus gentium* as early as the sixth century B.C. Certainly the institution of the peregrine court in 242 assumes the existence of a term with which to designate the body of custom which the court was expected to respect.

Similarly there can be no doubt that the recognition of *jus gentium* was associated with a respect for *aequitas* long before these two phrases occur together in Cicero. That the whole Roman federation was based upon the principle of *aequitas* is shown by the fourth century treaties of *aequo foedere*. And most of the strangers with whom Romans had to deal in the peregrine court were in fact members of states which had such treaties with Rome. The very aim of the institution was to prove that such treaties meant what they said even with respect to minute dealings between individuals. The historian of Rome must accustom himself to find Rome's deepest thought embodied in institutions rather than in philosophical formulas. In other words Rome had assumed and put into actual practise the principle that *aequitas* was superior to *lex* long before philosophic teachers had formulated a theory to that effect.

Nevertheless stoic philosophy also played an important role in the shaping of Roman law, though this came later. Stoicism in Greece took no part in politics until after Alexander's conquest of the East gave Athenians some knowledge of a great territorial state, and the subjugation of Athens itself suggested the desirability of a humanitarian philosophy with which to check Macedonian autocracy. Then it was that Chrysippus began to teach universal brotherhood and to insist upon the instinctive nature of justice and equity. That such theories should spring up among the misgoverned and suffering victims of tyranny is to be expected. But that the jurists of a proud and victorious people like the Romans accepted them as the basis of their law is more surprising. In his *De republica* and *De legibus* Cicero very explicitly accepts these stoic teachings, using them as a foundation for his political doctrine; and it was probably his friend Sulpicius, the keenest jurist of the day, who first adopted the stoic theory of a natural instinct for

justice as a basis for juristic philosophy. But Cicero is careful to show that Roman government had a definite historical continuity in native practise. He gladly adopted the new-found stoic phraseology, but he was well aware that in juristic as well as in administrative practise the principle had long been recognized at Rome that statute must conform to the dictates of *aequitas*. This is why Cicero is so ready to do deference to what he calls *jus gentium*, why he holds that justice rests on intuitive right reason and that law not based thereon has no real endurance. By the day of Gaius *jus naturale* is quite regularly the synonym of *jus gentium*.

The jurists, whose *responsa* were extensively rescued in Justinian's *Digest*, continued the work in the spirit of the republican praetors, drawing anew, however, from the stoic writings which were again popular in the second century A.D. Thus it came about that throughout the *Digest* discussions are apt to go back of laws, edicts and rescripts to principles of "equity" and "natural law," and that the code was based upon general principles which were universally applicable.

In international law a tendency in the same direction was hindered by Rome's rapid expansion. Here too a *jus gentium* (i.e. the accepted customs of nations in war) had sprung up, which, protected by religious awe, was well on the road toward an international code, when Rome's dominance interfered. Autocrats do not arbitrate within the sphere of their supreme control, and Rome controlled the world. However, in the early days of the federation Rome's principles in dealing with her allies had been very much like those which she expected to be applied in the Forum. And Roman writers like Livy and Cicero are not aware of a theory (popularized in modern times) that magistrates working in behalf of the state are excused from obeying standards of conduct expected of private individuals. The statement frequently made that Cicero considered Roman provinces national *praedia* to be exploited at pleasure simply is not true. In the passages that are usually cited to substantiate the view Cicero is not speaking of whole provinces but of limited public areas. It is not an accident that Rome's history reveals relatively fewer rebellions on the part of subjects than any other history of ancient times. Rome did not write an international code comparable to her civil code, but on her practises as recorded by Livy and Cicero, and on the apposite interpretations provided by the

Digest, the early founders of international law were able to base a respectable code of rules.

IV. GOVERNMENT. In the construction of their own constitution the Romans were far more apt to feel their way through experiments than to devise well-rounded documents on tablets like the Greeks. To one principle they adhered for many centuries: they felt that they were capable of ruling themselves and they rejected an absolute monarchy as unendurable. Every citizen must have a voice in the government. However, the early government laid the heavier burdens of responsibility, in the army as in the government, on those who possessed property and distinguished ancestry. The slow emergence of the plebeians, who at first occupied a very inferior place in the assembly, led through compromise—and compromise was distinctive of Roman politics as compared with Greek—to an illogical excrescence on the constitution, i.e. the tribunate with a separate plebeian assembly. In order to preserve a timocratic magistracy and lawmaking body without incurring civil war, the aristocracy, after two centuries of slow yielding, allowed the tribal assembly of plebeians who elected the tribunes (personal advocates of the poor) to assume full legislative functions (287 B.C.). Theoretically a part of the people—though a very large part—might now legislate for the whole. Perhaps the discrepancy in logic was excused by the fact that the tribunes as members of the aristocratic senate were conceived of as representing that body. Be that as it may, the important points were that the new assembly voted by wards without property qualifications, and that its acts were not amenable to senatorial veto. In theory, therefore, Rome was now ready to try absolute popular sovereignty. However, since all ten of the tribunes had to acquiesce before plebiscites were proposed, and since tribunes who offended the senate could readily be kept from political advancement, the possibility that this assembly would initiate radical measures was not great. It proved indeed to be a safety valve to prevent rebellion, a kind of popular referendum during periods of great stress, and finally it served in times of concord as a convenient body in which the senate could expedite needed legislation.

Soon after this assembly won its great power, the foreign wars began and the people, recognizing their limitations, quietly allowed the senate to assume responsibility and leadership. During that century (260–150) the assemblies

usually voted as the senate requested. In the middle of the second century Polybius, an intelligent Greek statesman who had lived for years at Rome, first as a political hostage, then as a friend of the Scipios, wrote down his impressions of the Roman government. He was greatly pleased especially with its “checks and balances”—a phrase which by a devious route has come to us from him. He observed that the executives were practically autocrats at the very points where power was essential, but that otherwise they were checked by limitations of time and by senatorial courtesy; that the aristocratic senate (the administrative body) had enough power and continuity practically to direct the policies of state without the liberty to go to extremes of conservatism; finally that the democratic assemblies (electoral and legislative) were in theory sovereign, though so well tied in by veto and parliamentary rules that they could hardly run amuck as the assembly of Athens had done.

Polybius is not far from correct in this description which, through its influence upon Cicero's writings, has also left consequences in modern politics. His observations were somewhat too much affected by Greek political philosophy, especially by that of Dicaearchus, who had advocated an ideal combination of monarchy, aristocracy and democracy. Fortunately for Polybius, he happened to see Rome at the very time when the senate was tacitly usurping functions beyond its legal powers, and when the Gracchans had not yet fully revealed the capacity of the assembly. He happened in fact to find something resembling the ideal state of Dicaearchus in operation.

In one respect Polybius' analysis came short of acumen, for by describing the Roman constitution in terms of Greek theory he somewhat dulled his own version and thereby hampered political thinking later. In Greek politics economic motives had played a very important role. Forms of government were associated with economic classes. When in Greece a political battle was waged between aristocrats and democrats, it was usually a battle between possessors and paupers, and too frequently revolutions resulted in a complete change of property. Polybius knew of dozens of revolutions of that kind. Hence he thought in terms of classes and functionaries representing classes rather than in terms of functions of administration. At Rome there had been class struggles, but the purely economic motive had never been strong enough to lead to bloodshed. Aristocracy had not as yet

become plutocracy. The senate was after all a group of ex-magistrates once elected to office by popular vote. The centuriate assembly which elected the consuls was not a horde but a gathering of citizens with votes weighted according to property. But the most important point that Polybius failed to recognize was the fact that the Romans had slowly built (unconsciously perhaps) toward a classification by function. In separating the praetorship from the consular office in 366, they had somehow discerned that judicial and executive functions were and should be kept distinct. In permitting the senate, consisting of ex-magistrates, silently to direct foreign policy and to become an administrative body, they had shown prudent comprehension if not acumen, for thus an administrative group grew up separate from the executive as well as the legislative group. And finally when they kept the old assembly chiefly as a conservative electoral body while allowing the tribal assembly to organize as a legislative body, they had again felt their way toward a wise division of functions. Had Polybius been a very keen observer, he might have made the fruitful distinctions recognized long after him by Montesquieu, who advanced from a study of Polybius to an examination of the English constitution. Cicero unfortunately followed the flattering description which Polybius had made, and Roman political thought suffered thereby.

The Gracchi also, too much influenced by Greek ideas, thought of the plebeian assembly as an organ of social redress, working in its own interest. They strove hard to reestablish the theory of popular sovereignty, whether or not with a view to greater reform when their immediate aims were accomplished, we do not know. At any rate their revolution inaugurated a new class struggle in which material ends came to be the chief prizes, and Caesar took advantage of the schism to vault into power.

V. HISTORIOGRAPHY. The attitude of the Roman annalists toward their records and their own observations changed from time to time. The beginnings are quite different from those of Greece. In Greece literary epic and narrative for popular consumption came early, whereas the keeping of full official records came later. At Rome the archives were stored with accounts, laws, treaties and priestly annals for three centuries before any one wrote Roman history for general readers. This distinction marks a difference which is worth observing in considering

the early annalists. In general we find in Roman historiography the following epochs that can be distinguished by general tendencies: (1) the period of the early statesmen-annalists before the Gracchi; (2) the period of the romantic popularizers working in the manner of Hellenistic writers; (3) the period of the antiquarian researchers in the days of Cicero and Varro; (4) the period of Livy and Tacitus, who while profiting from the methods and fruits of research insisted that history should be literature.

In the first period the writers were all senators who had been trained as lawmakers, judges and administrators. Schooled for their tasks in a day when there were no convenient compendia, they were accustomed to memorize the twelve tables word for word, and to keep in mind for use in senatorial debate the gist of the treaties made with scores of neighboring states. They were conscious of the importance of the official word. Of primitive legend there was, to be sure, no criticism, and when they chose to record this, as Fabius Pictor did about 200 B.C., they set it down as it came to them. But when dealing with the early republic, where some archival material was available, they adhered to it quite closely and avoided dressing it up with oral tradition. For the period that fell under their own eyes and the eyes of old witnesses still living they supplemented archival materials with what they saw or heard from reliable men. Although, in discussing the causes of contemporaneous wars and class contests, they naturally revealed the prejudices of their class and their nation, they seem to have made as serious an effort to be objective as they would have made on the judge's bench and in the council chamber. The antiquarians of Cicero's day found the books of these first historians exceedingly dry and crabbed, but recognized them as good storehouses of facts. Only fragments have survived from these writers, but Polybius, who based the Roman part of his valuable history upon them, has preserved the substance of their work for the century preceding his own activity. Since Polybius came from Greece at a time when historical standards in his own country were at their lowest, it is probable that he, despite a conviction that Fabius was sometimes blind to Punic arguments, learned his method and acquired his respect for the exact wording of records from Fabius, his chief source. Polybius, the foreigner, could readily attain objectivity in relation to Roman affairs and, having at hand Punic documents which

were not available to Fabius, he could correct Fabius. Unfortunately when he wrote of his own Achaeans he too was swayed by nationalistic prejudices which must be discounted to some degree.

The second period of Roman historiography marks a very serious decline. Primary education was now general and a growing public of readers demanded popular histories. Many writers sprang up to supply the need. Greek historical romances of the worst period were taken as models of how to be picturesque and dramatic. To get the necessary substance the writers searched out the legends of the heroic age that circulated in the households of old noble families. Many of these legends might have been confuted by reference to the archives, but if the legend was more interesting than the facts, it was too often preferred. We need not necessarily assume that the legends were far from the facts, for these families themselves possessed valuable archives of their own, two or three hundred years old, containing speeches made in the senate, minutes of senatorial discussions, sometimes also military instructions. Furthermore the Romans were legal-minded and were not given to inventing elaborately. But the point is that the numerous writers of the second period had frankly adopted the ideals of Hellenistic history, using no adequate critical standard for their work. Hence we are helpless when confronted with much of the history that covers the fifth and fourth centuries—the period which received the heaviest padding in the Gracchan days. We should also add that this was a time of very bitter class struggles when several of the leaders wrote autobiographies purely for apologetic purposes. And these also lowered the standards of accuracy and provided biased materials for later writers.

In the third period there was something of a reaction against the popularizing romancers, since men of better education had grown suspicious of what was being provided, and statesmen needed reliable books of reference. The encyclopaedists of Varro's day rescued from the archives much material which later historians could use. The methods of criticism, however, were not of the best, especially as linguistic science had not developed to the point of providing reliable criteria. And no great historian arose to demonstrate what could be done by adhering to exacting standards of accuracy.

Yet the wholesome effects of this period of research were not lost. Livy, who followed, was

not an antiquarian—he wrote with too great speed and he desired to produce good literature. He is not to be judged by his first books, however, for he frankly states that in this part the available story is legendary and that he tells it for what it is worth as a story. Here and there we find that he has made serious mistakes. And although he often makes a serious effort to be objective he is also very nationalistic, as all Romans were in his day. For biased judgment, however, he probably has no passage that can compare with Mommsen's amazing portrait of Caesar. What he has learned, even when he has not the patience to delve in the archives, is that for the historical period the popular story which passed current in his youth is to be checked up by the constant use of the dry early annals. That he had not time for independent research is comprehensible when we recall that his history was about twice as large as the first six volumes of the *Cambridge Ancient History*. His value lies in his employment of the best secondary sources for the historical period, in his ability to reproduce the fervor of Rome's political energy, and in his vivid literary art.

Tacitus had about the same attitude toward his sources as Livy, although he more frequently went to primary documents. His personal prejudices in the selection of material and in his partisanship are more patent; his dramatic qualities are given freer play; and his powerful style, adapted to satire rather than to historical narrative, reminds one of the more epigrammatic pages of Gibbon. After these two writers historiography again suffered a decline. The two Greek historians who wrote on Roman history later, Appian and Cassius Dio, followed the romantic tradition of Hellenistic history without its capacity for literary composition.

VI. MONARCHY. When Caesar had defeated Pompey in the Civil War, it was a foregone conclusion that he would not surrender his power as Sulla had done. The empire, stretching from London to Damascus, from the Rhine to the Sahara, must have frontier garrisons along a line of several thousand miles, and these garrisons must have an unquestioned master if the civil wars were to end. The primary assembly of citizens within reach of the Roman polls was wholly unfit to govern such a vast empire, the provinces were in no way ready to share in the rule through representatives, nor could they quickly be Romanized in spirit with the slow means of communication of that day. No more

could complete power be trusted to the senate, a group of jealous and ambitious nobles who had so long been severed from direct responsibility to the people that they had lost popular respect and confidence. The time for a monarchy had obviously arrived, but it was very dangerous to say so in the face of five hundred years of popular government.

Caesar forced the expiring government to grant him a temporary dictatorship, for which there was abundant precedent. Then he set at work discreetly to devise means by which he might wean the Romans away from republican traditions toward a monarchy that, unlike the dictatorship, might give him an unlimited term. Absolute monarchy seemed to be the only form that would be strong enough to override attempts at popular revolution and to keep all the armies in leash, and the history of Alexander and his successors taught Caesar that the only monarchs who had succeeded were those who claimed and imposed the claim of superhuman descent or inspiration. Mysticism and religious awe must be called into service. Hence, as Eduard Meyer has shown, Caesar, like Alexander, encouraged rumors of divine descent and invited the bestowal of divine honors. Before his death the senate had proclaimed him of divine origin and voted him the attributes of divinity. But Caesar had acted too speedily. The Romans (except for the urban rabble) were not ready for oriental mysticism. They might have grown accustomed to the required phraseology had Caesar given them time to find apologetic interpretations for it, but he was in a hurry to begin his conquest of Mesopotamia. The revelation of his intentions shocked the senate and he was struck down.

After thirteen years of intermittent civil war Augustus secured complete control of the empire by defeating Antony. He was too shrewd to invite disaster by following Caesar's road to theocracy, although in the first struggle he tried to profit by calling himself the son of the *divine* Julius—presumably hoping to be accepted in time as a divinity himself. However, after the world was tired of warfare and few of the nobles remained to resurrect old traditions of liberty, Augustus, made all-powerful by his victory at Actium, realized that he could take his time to work out an acceptable form, and that there was no need of offending the nobles. He then laid aside extraordinary honors and titles and, after some experimentation, decided to rule by means of the traditional magistracies,

using the proconsular office over the border provinces for the control of all the armies, and the tribunician power for the control of legislation. He could then safely permit the senate to continue as an administrative body in control of the government of pacified provinces which had no armies, and the republican magistrates could be elected as before to perform their duties within the circumscribed field now remaining. Nothing was defined regarding the succession, the question being left open in order not to offend those who still hoped that the theory of a republic was not wholly annihilated. But no one need have doubted that the man in whose hands Augustus should leave the proconsular command at his death would become his successor.

Mommsen has called this new government, designed in 23 B.C., a "diarchy," as though the world were divided under two associated and equally powerful heads; and Meyer, going even farther, has held that Augustus had in a real sense attempted to restore the republic—as in his *Res gestae* he claimed that he did. It requires a great effort of faith in forms and phrases to accept either theory in all seriousness. In 1927 there came to light several inscriptions from Cyrene, a small senatorial province, which show that in the years 7-4 B.C. Augustus not only freely gave advice to the senatorial governor of the province but that he reformed the local courts there. We have known, of course, that Augustus had the proconsular power in his own provinces and that he was also voted the *majus imperium* over the rest, but we had assumed that Augustus had avoided the exercise of this power except when invited to do so by the senate. It now appears that this *majus imperium* was exercised over the least significant senatorial province upon the slightest provocation. Augustus had in fact established a monarchy, distributing just enough offices and authority among the old organs of state to keep the senate content. And after a number of years (apparently about 12 B.C.) he again began to reveal aspirations for Caesarian autocracy. In the provinces assemblies were already holding festivals at which the deities "Roma" and "Augustus" were worshipped, and indeed temples were erected to them. In Italy there were to be no temples (though a few were erected), but the "Genius" of Augustus was to have a place with the public *Lares*, and the new cult was to be in the hands of a select group of freedmen in each city. Only after death, however, did Augustus expect the canonization, which Caesar had in-

vited while still alive, to take effect in Italy.

The imperial cult had some value as a contrivance for smoothing the way of government and eliciting devotion in the oriental provinces, where such things were customary, and among the freedman (ex-slave) classes in Italy, which were largely of oriental origin. It also had some influence in keeping the heterogeneous elements of the army loyal, since constant deference to portraits of emperors borne on standards was a daily reminder of the majesty of the person to whom the soldiers had sworn obedience. Among the old stock of Italy, however, the imperial cult never gained any real religious meaning. In the European provinces, from Greece to Gaul and Spain, it had just as little import. The occidentals went through the forms on stated occasions and raised honorific inscriptions as they were told to do, but in the home and in the private gatherings of the indigenous peoples the imperial cult never gained any real significance. The cult in fact seems to have been of dubious value west of the Aegean, and was doubtless imposed by some courtier who without due study had concluded that the mystical devotion observed in the imperial temples of Asia could be transplanted to the West. For two centuries the cult was generally confined to the "canonized" dead emperors, the *Divi*; in fact both Caligula and Domitian, who invited the title of *Deus* while living, met a violent death. Aurelian and Diocletian, who found the cult weakened in the army because of the civil wars that in quick succession had revealed the fragility of emperors, reorganized it among the troops by connecting it with the Mithraic religion, which was powerful among the eastern troops in the army. In this new cult the emperor called himself the representative on earth of the "Unconquered Sun," and himself a *deus*. Diocletian, who kept his capital in Asia, was the first who succeeded in ruling as a god. His successor Constantine, who recognized as legal the religion of his Christian subjects, could not consistently assume the titles of his predecessor though he did not refuse all the formalities. The later theory of rule "by grace divine" does not therefore descend directly from the Roman imperial institution, but was again invented to serve as a counterpart to the assumption of divine vicegerency by the popes.

VII. IMPERIAL ADMINISTRATION. The administrative machinery developed by the emperors differed much from the haphazard system of the republic in which consuls had

held office for only a year and could not, therefore, effectively supervise permanent governmental bureaus. Augustus, while feeling his way out to a more effective system, had at first employed the trusted servants of his own household as secretaries and treasurers of temporary departments of state. Since as proconsul he was excused by custom from rendering his accounts until he laid down his office, he in point of fact never did make a full statement for the *fiscus*, though he went far toward organizing it effectively. In the frontier provinces, where armies were needed, the emperor was proconsul. His place in the various provinces was held by his *legati*, chosen by him for indefinite terms from the senatorial class. These *legati* commanded the garrisons as well as administered the affairs of the province. Their judicial duties were not onerous, since the cities and districts enjoyed a large degree of autonomy and Roman law did not become operative until after Caracalla's edict. Needless to say, however, appeals to the governor became ever more frequent. The *legati* were usually chosen with care and held to strict account by the emperor and, as the tax gathering department was severed from the administrative, the temptation to abuse power was far less than before. Rome's provincial administration improved everywhere under this system, since the imperial appointees set a standard for the senatorial governors as well, and since the emperor occasionally exercised his *majus imperium* in calling to account any delinquent governor of a senatorial province.

The provincial tribute in the republic had usually been about a tenth of the crop, a single tax which was supposed to adjust itself over the cities since, when this tenth was shipped to Rome, the farmers could sell the rest of their surplus in the cities at a higher price. However, special poll and sales taxes were in time devised to catch the urban population. Much later, revenues from monopolies were introduced from Egypt. Julius Caesar had already gone far toward abolishing the tithe in kind because it entailed heavy costs in the collecting and invited dishonesty. Since he intended to do away with the annual change of magistracy at Rome, the time was ripe for the institution of direct tax collecting. The money saved to the state by the new system went to the taxpayer, for Caesar estimated the fixed tribute at about two-thirds the average value of the tithe.

The core of the army (over 100,000 men) was made up of citizen legions. These were sup-

ported by about an equal number of provincial auxiliaries who were given citizenship at the close of service. During the early empire conscription seldom had to be used. The pay was about the daily wage of laborers and, after twenty years of service, a grant of land or of money equivalent to about one-half the sum of the stipends earned. Army casualties were much reduced, since the imperial policy during the first two centuries was in general to protect the frontier and not to advance it. The principal legions were stationed on the Rhine, the Danube and on the Syrian frontier. After Vespasian's day recruiting for legions was seldom carried on in Italy. There were enough citizens and "Latins" in the provinces for the purpose, and the custom increased of enrolling suitable auxiliaries who were given citizenship when transferred to the legion. The army was perhaps the most important factor in the spread of Latin speech and of Roman customs.

Much has already been written about a putative imperial policy of Romanization and urbanization in the provinces. Direct evidence for this is very thin. It is, of course, a remarkable fact that in three centuries of Roman rule in Gaul, for instance, Celtic speech was almost entirely displaced by Latin whereas, fifteen hundred years after Roman rule, the one corner of France which later received an enclave of Celtic-speaking people still remains so largely Celtic in language. Nevertheless the evidence favors the old theory that the Roman government followed a policy of *laissez-faire* and seldom concerned itself as to whether or not the people in the provinces were adopting Roman speech and customs. In Africa, Spain and Gaul the stimulus seems to have come from the provincials themselves rather than from Rome; while in the East the native culture remained undisturbed. In Africa Rome's garrisons stopped seasonal nomadry in the interest of peace and security. As a result the nomads settled down to agriculture and, preferring to live in compact communities, they formed towns which invited trade and in time grew to the point where they could be granted municipal status. In Gaul the process was different. Here cities grew up near good harbors and at points where the army could conveniently receive supplies. But in the central part the Celtic tribal organizations long remained undisturbed. The Roman government did not concern itself with the nature of social organizations so long as the tribute was forthcoming. Normal economic processes gradually

divided the natives into large landholders (who invited Roman culture for social reasons) and renters. In Gaul the manorial villa with its group of dependents usually formed the nucleus of new cities. There were other ways in which Roman culture spread, but these instances will perhaps illustrate how without purposive pressure from Rome internal social and economic factors furthered the formation of Romanized municipalities.

VIII. ECONOMICS: IMPERIAL PERIOD.

The economic system did not alter much during the first two centuries of the empire. In the making of a few articles like pottery, glassware and bronzeware certain old industrial centers in Italy continued to produce large quantities for world wide distribution. Cloth weaving of wool, however, remained a domestic industry in Italy, and implements of iron and steel were usually put out by the individual smiths, though occasionally there was concentration of numerous smithies in one firm. In southern Gaul large factories sprang up for the making of glass and pottery, and Egyptian state factories, which had long made fine linens, continued to do so under Roman dominion. In a word, although capitalistic production was maintained, it did not make great strides under the *pax Romana*, despite its open ports, safe seas and extremely low tariffs. It is difficult to see why. To be sure, Roman law discouraged the formation of corporations of unlimited liability, but that law was not applied to foreigners. In Asia, Africa, Spain and Gaul non-Roman manufacturers had the right to form joint-stock companies to increase their production but they seem not to have done so. Capitalism was not kept down by heavy taxes or tariffs. There was no graduated income tax to frighten mounting dividends, and harbor dues ranged from two to five percent. Italy, of course, was devoted to agriculture and foreign investments in land, and never suggested the need of mercantilistic policies. The extension of the empire in fact opened the doors of Italy to foreign goods carried in foreign ships, and this was certainly one of the chief reasons why the larger Italian industries of the republic dwindled by the time of Marcus Aurelius. And those foreign goods were largely produced by slow free manual labor working in small units, as was the case with Anatolian rug weaving until recently. The world of trade, which had promised in the days of Augustus to create a new industrial era, settled back gradually to the old small-shop system to

which so many European cities still adhere. It was a harmless, congenial system which worked the artisan hard for small profits but left him a free individual; and it permitted the consumer to satisfy his own tastes without having to submit to the tyranny of standardized factory goods: the psychological explanation of it is not to be disregarded. The system, however, did not create much free capital to serve as a balance wheel at times of political crises, and during the empire sudden invasions always found the state lacking in economic resiliency.

With the establishment of the empire piracy came to an end, not indeed through any direct effort to police the seas, but because Augustus insisted on complete orderliness in the provinces, and it was in the misgoverned provinces that the pirates had fitted out their crews. Maritime commerce now increased. Ships were not large—indeed few harbors could have received large ships—and the emperors did not undertake to build harbors except at Ostia; but the Syrians, Alexandrians and Greeks in the East and the old Punic towns of Africa and Spain—especially Cadiz—shared in a very busy maritime trade. It was also about the time of Augustus that the periodicity of the monsoons south of Arabia became known, so that ships could sail from the Red Sea ports of Egypt to India and back by a route much shortened. A voyage from Rome to lower India and back was now considered quite feasible within a year, and it could be made wholly by water after Trajan connected the Nile and the Red Sea by canal. Indeed in the second century ships setting out from Egyptian harbors not infrequently visited the coasts of China. But since there was still no compass, shipping had to cease during the rainy season when the stars were usually hidden; and skirting the shores in order to keep directions entailed much danger of shipwreck.

Land routes were still popular with traders. And Rome was above all else an expert road builder. These roads were apparently never built primarily for commerce. They had been made straight and solid to carry the armies with their heavy baggage trains to and from the outer rim of garrisons. However, they had also been surveyed with a view to the speedy provisioning of the garrisons, so that they usually connected important cities. As a rule the government constructed the great thoroughfares and called upon the communities to build the connecting links which served for local intercommunication. Commerce, of course, quickly availed itself of

these open and safe arteries, and trading posts which grew into cities sprang up wherever they went.

In agriculture the drift toward large plantations continued in Italy except in the Apennines, where there were still many small holdings. Large farms often specialized in one chief product and depended upon the market for the clothing and implements needed. "Domestic economy" was not the rule. In Italy orchards, vineyards and ranches increased. In the neighborhood of Rome this was in part due to the fact that provincial grain came by way of tribute and was sold in the city below market price. In other parts of Italy it was in some measure due to the fact that the soil was weary of cereal raising and that the people had become accustomed to a more varied diet. With the rise in the price of slaves and a certain political objection to slavery—which we first notice in the legislation of the Gracchi and Caesar—the tenantry system was becoming increasingly usual on large estates. By Hadrian's day there were probably more tenants than slaves on Italian lands. On imperial estates, which had become very extensive through the brutal confiscations of Nero and Domitian—Septimius Severus later surpassed even Nero in expropriating property—the tenantry system was customary. On these estates an imperial contractor managed the plantation, supervised the tenants, collected and marketed the thirds which they paid as rental, and drew his own profits from the exploitation of a part of the estate which was worked without cost to him by the tenants.

Many of these renters were very humble people; in Italy not a small proportion were ex-slaves, set free and turned into tenants when it was noticed that compulsory labor on land was inefficient and expensive to watch. In the provinces many of the rudest and dullest of the natives were among the small renters. In the third century, during the fifty years of civil wars and invasions, the tenants suffered severely. Taxes rose and rents were increased to the highest possible point. Tenants then began to slink away from their holdings to such an extent that the emperor, in order to secure his returns from his own rentals as well as from the taxes on private land, issued an edict which ordered farm tenants to observe their contracts. When this did not suffice, another edict followed commanding the sons of tenants to take up the contracts of their parents. By this time the renters were already in such humble station that

they failed to rise in insurrection, and henceforth they were bound to the soil in quasi-serfdom. Of the exact process by which all this took place we have no record, but an edict of Constantine, dated 332 A.D., shows that the process was then nearly complete. Something of the same kind occurred simultaneously among the artisans when at a critical moment the state insisted upon the conscription of the labor guilds for government service. Then urban labor, as well as rural, had to accept a permanent status of bondage.

IX. SOCIETY: IMPERIAL PERIOD. Gibbon and Mommsen have pointed out that during the second century there was more general prosperity and happiness than the world had seen up to that time or was due to see again for many centuries. The number of slaves had diminished to such a point that the remainder were treated with much consideration. Even if stoicism and Christianity had as yet exerted little practical influence in teaching humanitarian doctrine (and neither went so far as to outlaw slavery), prudent considerations of self-interest advised the placing of slaves under the protection of the courts. With the decrease in slaves there was, before serfdom entered, an increase in the class of free shopkeepers, artisans and farm renters who, in view of the constant growth of the cities and the lavish expenditure of money, must have found life tolerable. Charitable institutions were so numerous that there need have been little suffering from want. There are many inscriptions that contain some record of foundations and trust funds devoted to the support of the poor, the building of schools, baths and theaters, and to the financing of public festivals. The state, too, was interested in such benefactions. Not to mention the "bread and circuses" provided to keep the poor of Rome in complacency, Nerva and Trajan also placed productive funds in the hands of committees throughout Italy to provide for the support of the children of the poor. This might be termed a motherhood pension, but since these funds were regularly invested in land mortgages the institution provided at the same time "rural credits" at a low rate. It has been estimated that the equivalent of about one hundred million dollars of state funds was thus placed.

Wealth was abundant in the second century and the rentier class enjoyed leisure in most of the cities of the empire, patronizing the arts, especially those that might contribute memorials to themselves. Pliny, who owned several exten-

sive estates, was a typical citizen of this period of prosperity. He held the usual offices of state, visited his properties, hunted, supervised and endowed charities, gave purses to impecunious writers, bought works of art, wrote salacious verses and moralizing letters and almost daily attended literary readings. An enormous amount of polite writing was done. If it were true that economic prosperity stimulates cultural production, that period should have created a dozen Shakespeares. In point of fact it created not a minute fraction of one. It filled gorgeous cities with busy, generous, contented epicures who were sure the millennium was just beyond the threshold. We now know that the thousand years which they inaugurated were the most dismal that history has recorded.

The student of sociology will find one of the greatest of mysteries in attempting to analyze this strange second century A.D., a period which displays a charming material façade over cultural futility. Art was floundering back and forth between baroque lavishness and academic exactness. In literature experimenters were trying the boldest effects in "new styles," while others were working on established models. In religion the new mystical cults gained many adherents, while the educated classes turned to every form of philosophy as a substitute. A kindly humanitarian stoicism had the favor of the court, but teachers of Epicureanism, of the Academy and of various forms of hedonism also had respectable audiences. There was diversity enough, and a widespread eagerness to find intellectual satisfaction, but no directing force, no definite cultural trend. It would seem that Rome, after pacifying the world and building the roads that connected east and west, north and south, was being overwhelmed by the confusion of faiths, creeds, temperaments and tastes that rolled back upon her. An absorbing fellow-sympathy and open-minded humanitarianism, neutralizing all initiative, seems to have been the only outcome of the all-pervading race mixture that was Rome. It may be that this might have proved to be a fermenting period for a new vital culture, had there been time for its emergence; we cannot say. It was at least futile in cultural accomplishment, and the government broke down before anything came out of it.

The only significant products of the periods were in the realm of jurisprudence. The rapid spread of citizenship, which culminated in the grant of universal citizenship by Caracalla, called for the adaptation of Roman law to diverse

peoples in all corners of the world. And the emperors called to their service the keenest minds of the age, men like Papinian, Ulpian and Paulus, to write "responses" in their names. These men labored in the spirit of the old republican jurists, endeavoring always to find a logical basis in "natural law" for individual decisions, and they were the more eager to do so because they were deeply versed in stoic thought and also knew the needs of the new peoples who had grown up under non-Roman custom. When long afterwards Justinian ordered the codification of all law, his jurists fortunately went back to these *responsa* as the soundest body of juristic thought. The result was that his *Digest*, which became the foremost textbook of later European jurists, disregarded many of the aberrations of the fourth and fifth centuries, which had made a different law for *honestiores* and *humiliores* and which had accepted the word of the monarch as absolute. The *Digest* reverted to the earlier theory that the prince's power was derived from the people, that all free men were equal before the law and that law was the science of justice. It thus became one of the most powerful factors making for modern liberalism.

X. ROME'S LEGACY IN THE FIELD OF THE SOCIAL SCIENCES.

In the social field Rome's thinking was generally reflected in practice rather than in philosophic discussion. Where patriarchal tradition is strong and where the organs of government are completely occupied with the administration of a world wide empire, one does not expect the government to take up the burden of social amelioration. Paternalism appeared far less frequently at Rome than in Greece, and is seldom to be found except in the empire. Caesar, eager to save the old stock of Italy, had attempted to enforce the employment of free labor on the farms and to colonize the urban freedmen in the provinces. Augustus, when he found that the family institutions were disintegrating and that "race suicide" seemed imminent, made some very drastic experiments in legislation, limiting the freedom of divorce, taxing celibacy and childlessness and giving rewards to families of three children. Then, fearing the consequences of race mixture, he placed a moderate limit upon the manumission of slaves. Now and then the socialistic theory had cropped out that the state must provide a living for indigent citizens, a theory which probably arose because the re-

public for a long time had had an abundance of public land available for anyone who was in need of a livelihood. The Gracchi had so far accepted the theory as to institute regular doles of wheat in the city for the poor citizens who could not be given land, and this became a regular institution. Nerva and Trajan went much farther, in that they created a large state foundation, mentioned above, which was at once a motherhood pension and a provision for rural credits.

However, it was especially in institutions of gradual native growth that Rome's social experiments reveal situations deserving of careful observation. The remarkable political aristocracy that survived for hundreds of years, based primarily upon unpaid distinguished civil service, stands out as one of the most striking phenomena of Roman society. To be sure, ancestry as an important consideration in defining the group and property qualifications were not disregarded, but in every case personal capacity in public office was the determining factor. This aristocracy, though it grew selfish and overbearing at the end, performed without remuneration very remarkable services at times of great stress. No less peculiar to Rome was the high position accorded the matron in the family. The family, tied together merely by a contract that could be severed by consent or by either member for good cause, nevertheless remained effective up to the time of the civil wars, resting as it could upon mutual respect. Not until ecclesiastical authority became dominant in the government of decaying Rome was the matron compelled to accept a different code of conduct with respect to divorce. Useful also for study is Rome's remarkable experiment in race mixing. Because of the heavy importation of cheap labor over the slave-block, which crowded free labor to the provinces, and because of the ease with which slaves entered citizenship through manumission, the population of Italy was largely transformed racially between 200 B.C. and 200 A.D. We do not yet know what this unparalleled displacement of a native stock had to do with the change of spirit that took place in the dominant state. Perhaps we shall never know; but the fact must not be lost sight of in a consideration of Rome's social experiments. There are those who consider it a very important factor in Rome's decline.

In the field of economics Rome produced no important writers. Yet the civil code bears the marks of sound economic thinking, especially in its respect for the rights of private property, its progressive handling of contracts and its de-

finition of partnerships and associations. For despite a certain distrust of corporations of limited liability, the Romans developed for civil purposes an adequate corporation law. Indirectly it was a gain for commercial law and precedent that the state which ruled the Mediterranean was so little concerned with the commercial success of its own citizens that—unlike Carthage—it could advocate open ports and the freedom of the seas. The examples of Rome's behavior that Grotius was able to draw from Livy made an impressive argument against *mare clausum*. As a striking example of national interference in economic laws, one may refer to the later imperial "conscription" of labor guilds and farm labor which led to the colonate of Constantine's day. On the other hand, the theory that slavery releases energy for cultural advancement—once advocated vigorously in our South, and not wholly dead—does not occur in Roman writers, though it is supposed to draw support from Roman example. The institution of slavery as found in Rome deserves very deep study from the economic side, for nowhere else can it be observed in its most natural aspects. On this subject R. H. Barrow's recent study, *Slavery in the Roman Empire* may be consulted.

Of Rome's contributions to the art of government the books of the eighteenth century—when modern political theories were taking shape—are the best witness. Rome provided several examples of governmental forms. The successes and failures of aristocratic administration and of pure democracy—a democracy somewhat saner in its behavior than that of Athens—could be studied in Livy and Polybius. The efficiency of the liberal monarchy of Augustus and the oppressive bureaucracy of Diocletian's absolutism are well described in the imperial writers. The outstanding accomplishments of the middle republican period have been among the most significant contributing factors to the building of modern states. Here we refer especially to the demonstration that liberalism in the administration of a large federation enabled an orderly democracy to win extensive cooperation from its neighbors. No less remarkable was the spirit of compromise—the willingness to "play the game"—that at Rome won a long series of class reforms without bloodshed. It was this capacity to see the other man's point of view, to yield by adaptation before striking, that finally created the constitution of "checks and balances" which evoked the enthusiasm of Polybius. Again, the record of a society submitting to the severest

discipline for the common good, a discipline that brought into being the Roman legion, that insisted upon durable roads, aqueducts and public buildings, and that took its share in the exacting civil service of Trajan's day—this record constitutes one of Rome's most lasting contributions to civilization.

The effects of Rome's territorial expansion were diverse. It was not wholly beneficial that one state should have become the carrier of a world's culture. The cultural rivalry that has arisen from a segmented Europe has been fruitful, just as it was productive of thought that Athens and Sparta worked upon separate theories of state and with differing ideals. World unity under Rome was in danger of creating stagnant uniformity, and there was also the danger that when the one cultural state fell, all culture would go under. The fact that the western provinces assimilated so quickly all that Rome could give is a demonstration of what value lay in unity. But against this must be matched the fact that this very centralization seems to have stifled rather than stimulated the frail and dying culture of Greece. As an illustration of the value of imperial unity, one may perhaps point to the rapid spread of Christianity. Taken simply as a cultural phenomenon it is difficult to see how a religion springing up in a nook of Asia could have spread over the civilized world in three centuries but for the fusion and confusion of peoples that Rome's imperialism had brought about.

In the domain of jurisprudence the early Romans did not indeed produce penetrating analysis, yet by combining a temperamental respect for law and order with an incomparable accumulation of experience in government which they patiently studied, they were able to evolve a practical code of universal applicability that more than matched the abstract constructions of the Greek thinkers. A prudently liberal self-interest, applied in the government of subjects as well as in participation in a world wide commerce, led them to respect the "customs of nations" and thence to infer the universality of a sense of justice before ever they learned that stoic philosophers had invented such ideas. They even preceded the metaphysical Greeks in creating such abstractions as juridical persons and corporations because their rapidly expanding state could not operate with the ideas of the single-cell *polis*. And conceptions created in order to facilitate intercourse with their municipalities were readily extended to other quasi-public

and to private bodies until corporation law was soundly based. Reading their experiences logically the Romans also conceived of the individual as a legal personality in his contacts with the state, and consequently assumed that the state conferred rights upon the citizen which must be protected by law even against the encroachment of the state. This is only one illustration of how the practical-minded Roman, averse to metaphysics, would nevertheless pursue an abstract idea to a very remote corner when experience compelled him to think. It was this practise of driving to the logical core of legal concepts that enabled the jurists to shape an enduring code. The permanence of their work is apparent when we consider that "most of the basic principles of the Anglo-American law of Admiralty, Wills, Successions, Obligations, Contracts, Easements, Liens, Mortgages, Adverse Possession, Corporations, Judgments, and Evidence come from the survival or revival of Roman law in English law. The fundamental conceptions of Habeas Corpus and Trial by Jury as well as many principles of the law of Torts are of Roman origin" (Sherman, C. P., *Roman Law in the Modern World*, 3 vols., Boston 1917, vol. i, p. 387).

Finally, though Rome's supremacy temporarily removed the possibility of what we optimistically call international law, her contributions to its code have been considerable. Until the civil wars shattered respect for custom, Rome observed strict rules of international dealings. It may be that the early fetial rules won a moral aspect only because morality was profitable to a people who had to be on the defensive. Nevertheless the spirit of the fetial law lived on in the customary rules of what was permissible behavior between nations in war and peace, a set of customs which was also called *jus gentium*. It is frequently said that those rules had not the force of a contract. But the fact is that they had a greater force than a contract that is broken as soon as a treaty is annulled. By a very old belief

Jove was the guardian of those rules, and whether or not the consul believed in Jove, he did not dare to permit his army to believe him accursed. Added to this was the fact that statesmen laboring in their offices for the state were still considered to be bound by the same moral code as when acting as individuals. The Hegelian theory of a state that is superior to the moral obligations which bind individuals may have been implicit in fragments of the code, but it was not made explicit and never was accepted as justification for international misbehavior. Accordingly it was possible for Grotius to connect the *exempla* from Livy with the sentences of the *Digest* and draw up a proposed code of international practise still superior in some respects to modern usage.

IV

The Universal Church

I. The Middle Ages may be considered, for our purpose, as starting with the reign of Theodosius (379-95) who, after a line of rather hesitating and ineffectual emperors, took charge of the undivided empire. The importance of his reign can be gauged from the fact that a year before his death he established Christianity as the religion of Rome and that he forbade any government official in the future to hold the pagan religion. The importance of this act can be better understood when it is remembered that the Christianity he "established" was that form of it which accepted the orthodox faith as determined by the popes. Some of the earlier emperors had supported Arianism. Theodosius proclaimed the Catholic faith in 380, declaring it to be the law of the empire that all his subjects should hold "that religion which the divine Peter gave to the Romans and which it is clear Pope Damasus follows and Peter, Bishop of Alexandria, a man of apostolic holiness." We can fairly look on the public and political triumph of the papacy as the dominant historical fact in that age. Through its rise and consolidation the failure of the Roman Empire lost much of its danger to western civilization. There grew up in place of that empire a central power around which could be grouped the fortunes of the new political organization that emerged out of Christendom.

The disintegration of the Roman Empire was inevitable—"the inevitable decay of immoderate greatness." The specific causes to which it was attributable have been the subject of a good deal of speculation; but in several directions there seems to be something of a consensus. Rome's dominions had expanded too widely for them to be defended except with an immense army; and though the organized armies of most of the provinces were undoubtedly valuable from a military point of view, the East, where most of the trouble was to be met, never did its fair share in furnishing recruits to the Roman arms. The eastern provinces, while accepting the imperial ideal, would never fight for it. On the other hand the Roman administrative system

could not be easily imposed on the western provinces. In Gaul, for instance, the Roman municipal system never took root; the tribal system in existence there, ancient, customary and vigorous, would not accept the restrictions imposed on it. Therefore, while Gaul provided the most numerous military recruits for Rome and the most successful in war, it was always the center of revolts and disturbance.

The economic basis of Italy was being undermined by transformations in the agrarian order. The conquest of the great grain districts of the world had made wheat imported into Italy so cheap that Italian small holdings had languished and finally had given way to enormous grazing farms with the usual sequel of unemployment. The price of slaves went up so high that they could not be used economically on the latifundia. The small landholders were therefore no longer dispossessed, but remained as servants of the overlord who had purchased them. In this way a new class came into existence, a servile population locally employed, attached to a farm, dependent on a superior lord, and falling into a customary service for which it received in return food and a home. But although these farmers stayed on and were now in subjection, they had no longer the same interest as before in the land they cultivated. The land itself became exhausted through the lazy ignorance of the worker and his failure to continue that orderly rotation of the crops and general art of agriculture which figured so charmingly in the "Virgilian litanies." Italy itself came to be on the edge of starvation.

At the very time when the country was poor the bureaucracy was extravagant in both size and spending. Moreover the old landlord class had largely failed with the collapse of agriculture at home, and its place was taken by a new, wealthy industrial class that did not trouble itself with local responsibilities, refused to continue the unpaid public service formerly ungrudgingly performed by the aristocracy, and thus drove the municipalities into either debt or increase of taxation in order to support the social services which up to this time had been

carried on without any expense to the public.

Under the financial difficulties and burdens thus beginning to weigh heavily on the ordinary populace, and still more under the unsound economic measures (debasement of currency, etc.) passed by the later emperors to remedy the ills, the restless population began to wander from their districts in search of surer and less oppressed conditions. Laws were therefore passed forbidding first the imperial tenants and later any tenants to leave their holdings, and also forbidding the guildsmen to leave their guilds. The enfeeblement of the empire was becoming obvious to all who lived in it.

Then came the series of invasions. At the outset Theodosius rendered service to Rome by inaugurating the new principle of settling the barbarians in the empire, but the failure of his successors to follow this policy was among the complex set of causes which led finally to the disruption of the empire.

II. The stage of western Europe was left to the papacy, which, together with the empire and Mohammedan power, shaped the course of historical evolution in the Middle Ages. The emergence of the papacy was most clearly seen in the life and work of St. Gregory I (590-604), surnamed the Great, who was forced to deal with the Lombard invaders as though he were a sovereign and indeed as though he represented the old power of Rome. His tribune protected the inhabitants of Naples from tyranny, his commanders defended Sardinia, and his ships carried from Sicily the grain needed by the Romans. Moreover his domestic policy favored the old established *coloni*, so that he was able in some degree to restore Italian agricultural prosperity. His short reign of fourteen years is typical of that public and political guidance given by the early popes to the West which saved it from ruin. Still another sign of their width of vision can be seen in the more spiritual side of the pontifical policy, namely in the vigorous effort to convert those newer nations which had never known the Roman discipline and were destroying the old Roman order. The British bishops who refused to attempt to convert the Saxons represented in their views a considerable body of Christians who looked on the faith as only coterminous with the empire and who therefore refused to regard as worthy of faith those who had brought destruction on the empire. It was against such an attitude that, two centuries earlier, St.

Augustine had written his *City of God*, of which one thesis, at least, was the right of the new nations to the inheritance of Christ.

The conversion of the Anglo-Saxons by the other St. Augustine (597) and finally by the Irish monks, and of the other newborn nations, inevitably added to the public greatness of the papacy. These newer peoples cared nothing for the eastern emperor nor for his exarch at Ravenna; for them the outstanding figure in Europe was the pope. It was the pope whom they traveled to Rome to see, and it was around the tomb of "the divine apostle Peter" that their own tombs were laid.

Even the literature of Rome, which retreated to Ireland during the invasions of the continent and of Britain and which returned again to the continent through England at the time of the renaissance under Charlemagne, represented no longer the language of old republican or imperial Rome but a new language. It had lost its old technique and some of its older grammar and syntax, but it had become more flexible and more vivid. It was now fit to inaugurate the *dolce stil nuovo* of the Middle Ages.

The Mohammedan influence began after the Hegira (622) when Mohammed fled from the pagans who were roused to fury by his preaching, only to return to Mecca in triumph eight years later. Surrounded only by disunited and disorganized peoples, the new religion found success easy enough; it went out to its apostolate with a sword in its hand. By the eighth century Christendom was ringed by a steadily advancing circle of Arab Mohammedan states—Syria (conquered in 634), Palestine (637), Egypt (640), North Africa (695) and Spain (711). Even here Mohammedanism did not seem to have found the limits of its domain, for though it was crushed in 732 under the walls of Tours by Charles Martel, its armies remained encamped on some of the southern districts of France (whence were later to come the heresies of the Albigensians) until Charlemagne drove them out nearly three-quarters of a century later. One effect of this circle of enemies was to keep Christendom together under the menace of invasion.

There were troubles, however, within Christendom. In all the West, besides the papacy and the distant islands, there were only two important secular powers—the Lombards and the Franks. These were both Catholic peoples, but with both the papacy continued an intermittent strife. By the eighth century the

greater part of Italy was thoroughly under Lombard domination, and the greater part of old Gaul was under the rule of one or another branch of the Franks. The Burgundians were a lesser people farther south who were later to emerge into prominence with apparent capabilities for achieving real nationhood.

Meanwhile under the old name of Rome an entirely new empire had been organized on the shores of the Bosphorus. When Constantine the Great had transferred thither the central authority of the empire (330) his object had been to establish government where it was most needed, within striking distance of the weaker frontiers, the Danube and the Euphrates. It was here that the undisciplined hordes of the outer paganism were most likely to attempt to break in. The new seat of government was to be a bastion on the defensive wall against the troubled East. While Constantinople always remained imperial, it ceased gradually to carry the old Roman character and became slowly impregnated by Greek ideas. More swiftly than Rome itself it became wholly Christian. By its complete intermingling of elements, Roman, Greek and Christian, the eastern portion of the empire continued, in a character entirely its own, the work of old Rome. This it did largely through its inheritance, first, of centralized government and of jurisprudence and, second, of the function of defending the common culture against an outer world. Of course, to the end, in the mind of the Byzantines and of the westerners themselves for a very long time, the empire was never a divided one, even when two emperors ruled separately over East and West. This division was part of the old scheme of Diocletian, intended to be merely an administrative division and not to imply a political separation of independent powers. In point of fact, however, the two parts of the empire were forced off from each other by the inability of the East to show any effective power in the West except spasmodically. Justinian (527-65), almost alone among the emperors, managed to make his power felt in the West.

The germs of both the weakness and the strength of the eastern empire were contained in its imperial inheritance of centralized autocracy. Thus in Byzantium a strong emperor was able to effect union, while a weak and incompetent emperor could do nothing at all. The lack of feudalism or some such wide-flung decentralized organization made it impossible for the emperor to gather a baronial council to his aid

and still less a legislative body or a band of advisers. In this way the nobles, shut off from constitutional methods of protest or advice, had no other way of meeting imperial oppression than to submit or rebel. The result was that the imperial line had an unhappy record of revolt, mutilation and murder. Yet the old bureaucratic system inherited from the Caesars alone held together the Byzantine Empire; it was enlightened, industrious and orderly. Although under a weak emperor little was ever effected, within or without, the empire continued as a whole to be perfectly stable and tenacious throughout all this period. Even at the end of the period when the Normans (1096) and the Venetians (1203) attacked it and were able to tear off provinces from it, setting up within its old borders princedoms of their own, the administrative success of the bureaucracy prevented any internal weakness from destroying it as would certainly have happened under similar circumstances in any corresponding state of the West.

The particular importance of Constantinople in our study is the importance of an alien example over against the adventurous West. With their inexperience and restless constitution making, the feudal states of Europe recognized the success of the long-lived autocracy and even tyranny of the eastern emperors. Always by their side was the spectacle of a political organization continuing to exist without having the support of much greatness or success other than hereditary greatness, the accumulated and stored wisdom of the past and the persistence of an efficient civil service. Moreover the personal government of the emperor included a sway over the church which, while it shocked the crusaders, at least gave new ideas to a Barbarossa or a Frederick II. Not merely did Frederick II have his Arab friends to point out to him the greater political power of a sultan who was also a caliph, but he had as well the rumor from the East which told him of a Christian sovereign who was also the supreme head of his church.

Apart from their interference with the creeds, the emperors undoubtedly provoked among the later national kings in the West an admiration for their system of government. French and English sovereigns cited the emperor by name as their particular ideal. His government was orderly and stable; they envied him his venerable power (*cf. Orient et occident* by Jean Eversolt, Paris 1928). We see

that influence reaching France through trade, through a desire to possess the rich relics of the saints to be found in the East and of course, later, through the crusades. But even before the crusades the prestige of Byzantium in the sixth century, the rise of the Mohammedan armies in the seventh, the modifications in Islamism in the eighth and the routes to the Sepulcher in the tenth and eleventh centuries kept the connection between East and West real and intimate, and enabled some knowledge, not wholly apocryphal, of the eastern empire to reach and inspire the kingdoms of the West. The naïve accounts of their visit left by the crusaders and the comments of Anna Comnena prove the influence of Byzantium on western political and social utopias.

A weakness of the eastern emperors was their inability to make use of the popes. On the whole, the papacy was for centuries true to its political allegiance to the East and remained true even when the Lombard had overthrown in Italy the representative of Byzantium and, boasting himself a loyal Catholic, claimed to be independent of the semi-schismatic East. The emperors themselves forced the popes from their submission and by their poor statesmanship drove into opposition the only power of the West that had any inclination to accept their sovereignty. In 751 the Lombards destroyed the exarchate, in 754 the Franks marched on the Lombard capital of Pavia, and in 757 the pope received the Donation of Pepin, leader of the conquering Franks. From that moment the temporal dominion of the popes was a public fact, recognized publicly and publicly proclaimed.

Within a generation of this act the popes had replied to the Donation of Pepin by transferring to Pepin's son Charles the empire of the West. As Charles knelt on Christmas Day in the year 800 at the shrine of St. Peter in Rome, the pope (Leo III) came over to him, placed on his shoulders the purple robe of empire and on his head a golden crown. Thus came back to the West a Caesar, this time appointed by the pope although acclaimed by the people. Not that anyone then thought of the pope as the political master of the emperor; the pope himself had been protected by the emperor and reinstated by him, and indeed on Charlemagne's election the pope, in token of his own political submission, had sent him the keys of the tomb of St. Peter and the banner of the city. Yet the fact remained embedded in the memory of

Christendom. The successor of Peter had transferred to the Franks the empire of the Caesars. The relationship of these two powers was to cause trouble enough later, but Charlemagne in his greetings to the pope after his election in 795 had already expressed his view of their relationship: "It is ours externally to defend the church and internally to fortify it by acknowledging the Catholic faith; it is yours to pray for the victory of Christendom and the magnifying of the name of Christ." But the problem could not be posed so easily as that. Under the Carolingians, however, the difficulties were few, largely because the successors of Charlemagne were never great enough in actual power to come in conflict with the papacy.

When, however, Pope John XII transferred the empire from the feeble descendants of Charles to the new Saxon dynasty, crowning Otto I in Rome on January 31, 962, the way was open for a quarrel, for there were many new features in this later Europe that made spiritual and temporal loyalties sometimes difficult to adjust. The German princes, for instance, used the church to extend their German dominions ever eastward and to find princely benefices for their younger sons. Thereby the new feudalism forced these prelates into a double subjection: as prelates they were under the jurisdiction and appointment of the See of Rome, as barons under the jurisdiction and appointment of the emperor. These conflicting claims soon involved a breach of the peace. Both sides had reason in their quarrel. Thus Gregory VII stated boldly, "The pope is master of the emperors"; thus Alexander III, in view of the facts, not unreasonably asked, "From whom does the emperor hold the empire if not from the pope?"; while Innocent III answered the question with complete assurance: "It was the apostolic See that transferred the empire from the East to the West, ultimately because the same See confers the imperial crown." These statements of course were true; the popes had certainly proclaimed, anointed and crowned this later empire, since there seemed to be no other power that could do it. The popes were thus recognized as the public voice of Christendom with its responsibilities and its greatness. Adrian IV, the Englishman, declared that he loved the tiara "*because it burnt like fire.*" Yet there was no tradition in Christendom that the pope was a temporal sovereign except over definite territories and then only by the grant of an emperor, as in the case of the fabled Donation of

Constantine or the more real but no less mysterious Donations of Pepin and Charlemagne. Between these two sets of facts it was difficult to find a solution of the problem. Each of these two supreme, though differing, powers had often requested confirmation by the other. *There seemed an age-long custom that neither was to be recognized until the other had approved.* Hence the conflicts between them were violent and significant, arising over such questions as investiture, the alleged right of the papacy to recognize and authenticate temporal sovereigns, the alleged right of the emperors to nominate the popes, the power of the crown over criminal clerks and, a little later than our period, the right of the crown to tax the clergy. But the source of most of these later disputes was the system of feudalism that was now rebuilding the world.

III. Feudalism is a system that is to be found everywhere as a stage in social development, though the exact form it takes will differ with the variety of local custom and even local religion. It was based on the principle of commendation by which one man took charge of another or put himself into another's charge. From the point of view of its duties it was a contractual system whereby the nation, represented by the king, let out its lands to individuals who paid rent by doing military service and civil suit; and as regards its rights it was a land system whereby, in Stubbs' phrase, "every lord judged, taxed, and commanded the class next below him."

Supplying a cohesive force when none other was possible, this system further introduced a wide sense of legality where everything was settled by custom and law and little was left to choice. Moreover it provided an armed force of provincial and even national usefulness which saved Christendom from invasions from both East and West. It solved for a time two of man's perpetual problems—his social organization and his land system. But it demanded a heavy price for these advantages, for under this system the central government lost touch with the lesser people and directly commanded only its highest vassals. On this account the cohesive force often proved useless. The independence and local sovereignty which the feudal system accepted encouraged civil war, and it was a matter of mere chance whether a rebellious baron might not have as many followers to his immediate call as had the king himself.

France and Germany were glaring instances of this. The entanglement of the church in the system prevented it from acting as a restraining force, and the perpetual dynastic controversies swept the bishops and clergy into one side or another, and soon degraded excommunication by making it not the least effective of the instruments of war between baron and baron, or king and king.

Besides feudalism, however, there was another world wide system that bound Christendom together—the institution of monasticism, which was gradually becoming a more tightly knit organization. At first St. Benedict and the Irish monks were its two chief representatives; to them more than to any other power, except perhaps the papacy, was due the recovery of the culture of the West, for it was in the monasteries, on their hills or in their remote deserts, that the tools of civilization—art and books—were to be found. In addition there was the great sprawling canonical organization, in which each house was even more independent than those of the Benedictines and accepted the vague and indeterminate rule of St. Augustine together with some local constitutions usually drawn up by the ordinary of the diocese. These canons regular and monks of various kinds were contemporaneous from the fifth century onwards and between them formed the chief centers of Christian piety and intelligence. They represented different ways of Christian life, being unlike in their ideals; while the canon was essentially a cleric and even a priest, the monk was not necessarily a cleric and at first was very seldom a priest. Indeed St. Benedict in his rule obviously looked on the priest as an unusual feature of the monastery. Hence it happened that while the monks preserved the older learning and were artists, architects, writers of chronicles and commentators on Scripture, the canons were the pioneers of theology. St. Augustine (430), their first promoter, was the great theologian of the church and his followers continued his work of illumination and thought. To St. Benedict we owe the culture of the West, to St. Augustine its philosophy and "divine sciences." Thus curiously it will be found that both Paris University and Oxford University began with a group of Augustinian canons and that the Lateran Basilica, too, had its theological school formed in the same way. Even the hospitals of the Middle Ages were chiefly Augustinian, including the famous ones at Smithfield and Bruges

and high up on the Pass of Great St. Bernard.

More, however, than the earlier form, it was the later developments of monasticism, Cluny and Clairvaux, that actually welded Europe into one. The earlier form, as St. Benedict saw it, was a series of independent abbeys, held together only by community of spirit, ancestral leadership and a rule. But these newer forms, born in an age of organization, were consolidated into a unity of government and visitation. They were new also in that they aimed chiefly at an intellectual ideal; the monks were now to be scholars, and the older ideal of mere monasticism gave way before the intellectual vigor of the time. This very eagerness, however, proved in the end their undoing. The monasteries were crowded, but not all could satisfy themselves with books or learning. For the rest new liturgical offices had to be created to keep them occupied. Thus the tenth and eleventh centuries are the period when the most elaborate Catholic ceremonies and a multiplication of votive offices were introduced. Religious zeal thus turned into formalism and in the end declined.

The earliest of these new monasteries was Cluny which, establishing its system under the name of "the customs of Cluny" (910), was a congregation of abbeys joined under discipline and placed under the power of the abbot of Cluny to correct and amend. Its most famous abbot was Peter the Venerable (1156), the friend of Abélard. Also to the same Burgundian province where Cluny was, came Bernard of Cîteaux (1153), the great leader of another organized form of Benedictine monasticism. Its "charter of charity" laid down the principles that were to govern it, and among these were poverty in life and worship, remoteness of site, agricultural work (i.e. not the clerical sciences), coordination of all the monasteries under Cîteaux, and then annual visitation of all of them by the abbot of Cîteaux, himself to be subject to correction by the abbots of the four oldest daughter abbeys.

The movement undoubtedly gathered most of its first fervor and importance from the leadership of St. Bernard. Although he was preacher, mystic, saint and scriptural commentator, he came nevertheless, as perhaps no other saint had come since Gregory and before him Augustine, as the public champion of Christian ideals in every form—in politics, in philosophy, in agriculture, in art, in war. He was not great in all these ways, to be sure, but he insisted on the need for Christendom to

remember that its only justification in such worldly activities lay in its devotion to the faith. An age eagerly waking to the stirrings of the spirit in man was swiftly reaching out in every direction for things new and wonderful, in art and thought and political thinking. St. Bernard stood for these ideals, too, but only as inseparably united to Christ. Although, as we read his works, he seems to us sometimes to have misunderstood his age—the philosophy of Abélard, the royal dreams of Henry II, the rich effulgence of the early artists—nevertheless he did point to the danger of these pursuits and their disruptive tendency unless pursued in harmony with the general ideals which their promoters professed to serve.

While monasticism thus helped to unite Christendom, a contributing force equally characteristic of its age and in its way no less effective, was the adventure of the crusades. The geographical results of the first three crusades were of little permanence or importance. However, the crusade effected the holding off of Islam and the coalition of all Christian princes in a sense of common brotherhood. These adventures also served to introduce into the West elements of eastern and Greek art and literature. Not the least of their effects was the undying memory of a great spiritual romance which survived out of all the failure and distress of the campaigns, and gave a common note of splendor, width of vision and faith to the poets of the time.

While many influences were working to make the unity of Christendom apparent, the vigor of heresy was no less evident, so that for the first time men began to be afraid lest this unity should be broken. The last Christological dispute was settled when Monotheletism was repudiated by the church (Council of Constantinople, 680). The next great point was the discussion of Berengarius on the doctrine of the Real Presence, culminating in the definition of transubstantiation as the orthodox statement of the mystery. Berengarius (1088) denied the Real Presence of Christ in the Eucharist, because his particular philosophy denied the possibility of any separation between form and substance. Lanfranc (1089), whom Berengarius had hoped to have as his ally, was his most vehement opponent. The dispute turned on a philosophical question. It was not a point that in itself ever roused or interested the common people. Such purely abstract discussions, except where it was felt that they

might somehow weaken popular devotion, were left to the emergent scholasticism as topics for dispute. The attacks of Peter Abélard (1142) on his old masters also roused only academic opposition. It was not mere freedom of discussion that he demanded. Mediaeval scholasticism had this in plenty. Nor was he a freethinker: "The rock on which I have founded my conscience is that on which Christ has built His church." His point was a much more subtle one, namely that philosophy might be able to deny what theology had taught. He wished to divorce altogether Christ and reason, faith and science, and believe what his own logic could prove to be untrue.

The other great center of disputation was the violent group of eastern religions that grew up where the Saracens had settled in the wide rich plains of the Touloussain. There the whole position began with a principle in violent conflict with the doctrine of the incarnation, namely that matter and therefore all material things are essentially evil. It was not even Mohammedan but Zoroastrian. It was the old gnosticism that had first captured and then repelled the imagination of St. Augustine, a permanent frame of thought that has haunted even the idealist followers of Christ. The heresy of the Touloussain became the focus of other points of dispute. The princes whose names were involved in the common condemnation of the heresy were always anxious to deny that they subscribed to it, and their opposition to the crusade against the heretics was due probably to the fear that their own political independence would be threatened by the papal army. Pope Innocent III (1216) alternately coaxed and denounced Count Raymond of Toulouse, while Count Raymond alternately denounced and coaxed the heretics. But Christendom was chiefly struck by this heresy because it was the first since Arianism that really threatened to involve the West in any serious loss to common Christendom. Furthermore it was not amenable to apostolic preaching, even by St. Bernard, and it was growing wealthy. The sudden fear thus engendered began the new era of the inquisition. Force is nearly always the result of fear. The use of suppression was new because the fear was new. From that time on, the menace of this heresy hung threateningly over the Christian world, and the idealist writing thereafter regards the apparently solid unity of Christendom as being once more in danger.

IV. The system of education had badly lapsed during the long era of the invasions except in the western refuge of Ireland where the apostolate of St. Patrick (464) had prepared a way for the only Roman conquest Ireland was ever to know—its conquest by the Roman faith. Here monasticism found in the impulsive and aloof spirit of the Celt a rich soil for its development, severe, vehement, artistic and missionary. Almost at once it became the refuge of western culture. Classic literature, which Augustine had studied and Jerome had feared, became in the end the possession of the Celt. He grappled with the inheritance as he received it, and restored it to the West a new instrument for a new purpose. By the time the empire had begun to fail, conversational Latin must have been very different from the golden literature of the Augustan age or even the brilliant paradoxes of Tacitus. In the next generation the language must again have declined, if we are to take as a fair example of it Jordanes the Goth (551), the chronicler, with his cumbersome solecisms, which yet manage to make his story live. Between his style and that of Boethius (524) or Cassiodorus (575) there is a great gap. It is Cassiodorus, the founder of the trivium and quadrivium, who was the master of mediaeval education, and he brought to his task a learned, overornamented and not very satisfactory Latin. Yet at the end of our period, by careful use and especially by austere thinking, a language had been formed out of Latin suited to express clearly the abstract notions of philosophy. Latin had always been rhetorical rather than philosophical. Now its rhetoric was replaced by a frugal diction expressive of sustained and logical argument.

Apart from philosophy, mediaeval education included exercises in "rhetoric." This was one of the subjects included in the trivium; it involved a certain acquaintance not only with such classic authors as Virgil, Horace and Ovid, and with post-classic writers like Seneca, but also with the whole field of patristic study, especially St. Augustine. How beautiful the mediaeval use of words could be, how much like Tacitus set to music, is evidenced by the liturgical prayers and some of the more exquisite hymns. Beyond these sweet and woven sentences packed with sense and fragrant with hints of Gospel and classic intertwined, such as the *Media vita* from St. Gall or the *Laetabundus* of Sedulius, there came the first hints of our modern languages. In the northern sagas, the

song of Caedmon and the Arthurian cycle we have the early stirrings of poetic muse; after them came unrivaled pieces of fairy beauty like *Aucassin et Nicolette*, or trumpeting battle songs like the *Song of Roland*, or the later sagas and the *Anglo-Saxon Chronicle*. There is also a Celtic literature of Ireland, Wales and Brittany, touched with sadness, brooding usually over the sea and the sea birds, or speaking with Greek delicacy of nature's beauty and the lift and fall of the passing seasons. All these hint at what we know already—that popular education was gradually climbing up under the inspiration of the monks and the growing schools of grammar and logic. Just how learned or unlearned were the people we shall perhaps never know; it cannot well be maintained that the age which planned and built and lived under the shadow of Chartres Cathedral was really brutalized and ignorant. Printing has completely altered and falsified our standard of education; we imply by the word illiterate that those who cannot read or write lack education. But that is only because we now limit education to a knowledge of facts, instead of seeing as its purpose the production of good taste. Taken at his best the dweller in the Dark Ages and in the early Middle Ages was above all a man of taste. Not even the thirteenth century can rival the twelfth in taste, although it surpassed it in dexterity and skill; the tenth and eleventh centuries show the spirit of man climbing up to the heights he has often reached before and after, but perhaps with a depth and richness and sound fancy that have never been eclipsed.

In the realm of thought, although we find much coarseness and truculence of expression, we can see minds hard at work grappling with problems sincerely and truly. It was never an age of servile submission either to popular taste or to hierarchic discretion. The early schoolmen worked steadily at their problems—Johannes Scotus Erigena (875) with daring, Lanfranc (1089) and Anselm (1109) with a richer feeling, Abélard (1142) with a swifter and more incisive wit, the great Victorines (Hugh, 1141, Richard, 1173) with a more mystic understanding. Ambrose (397) was familiar to them, and Augustine (430), to judge by the many quotations from his works, must have been known by heart. Gratian the monk (1151) inserted St. Augustine in great pieces in his *Decretum* and thereby influenced all the ages to come. So finely were the principles of war and peace settled by St. Augustine that modern social

primers often quote him verbally, not knowing whence they have borrowed their phrases and explanations.

Certainly such schools as these, grouped by chance around monasteries and cathedrals, and such instruction as could be picked up in the parish churches were gradually forming the minds of the leaders of the people. In his *Institutions of Divine and Human Study* Cassiodorus (575), as we have said, laid the foundations of education—indeed of our own education—since he bequeathed to the mediaeval world the trivium and quadrivium. It was through him that the Middle Ages touched hands with the older world. Nor was he content merely to describe education in the abstract; he described only what he had actually begun to do. He wrote out of experience. Although he was no Benedictine, his influence was no less important on that account; he started the mediaeval world on a system of education based on literature and the arts. This was widened through Spanish influence. Europe was especially affected by two Arabs, Avicenna (1037) and Averroes (1198), and two Jews, Avicbron (Ibn Gabirol) (1058) and Maimonides (1204). When we look for sure proofs of schools and a *scolasticus* (Paris University does not properly begin until after our period, in 1215), we find a definite system in existence before Charlemagne, with studies and a curriculum apparently in undisturbed possession as though it were a venerable and already well-worn thing. How it grew we have not yet discovered; that it was already operative in the seventh century we know. The greater names, besides those we have already mentioned, are Isidore of Seville (636), Bede (735), Alcuin (804), Rabanus Maurus (856), Luitprand (972), Gerbert (1003), Fulbert of Chartres (1028), Alain of Lille (1203), John of Salisbury (1180) and Anselm of Laon (1117).

V. The study of canon law toward the end of our period developed not merely education, clerical and lay, but also what there was of social science. By the eleventh century there were already very rich collections of decrees and decisions, drawn from everywhere, canons of general councils, papal letters, extracts from the fathers and the *Liber pontificalis*, anecdotes, even tags from Roman law, some genuine and some forged by Frankish clerks. These decrees and decisions are naturally concerned with the very matters that interest us: the social rela-

tionships of men, adjustable and to be adjusted, marriage, property, trade, usury, competition, wills, crime. Moreover general propositions bearing on the relationship of law to custom, of general law to particular laws, of common law to local privileges, were discussed by unnumbered commentators. Clerics whose business lay with particular men and women (whose lives were known to them to be full of difficulty) are found endeavoring to bend some rigorous phrase of Roman law or barbaric usage to suit a hard case come up for adjudication.

Roman law itself had lingered on in southern France and in parts of Italy, surviving in a more or less corrupted style. But the later introduction of the *Corpus juris* of Justinian, largely under the inspiration of Irnerius of Bologna and also his four disciples, Bulgar, Martin, Hugh and James, threatened to overwhelm the old barbaric usages and the capitularies of the Frank and Lombard kings. The detailed study of Justinian's work shows that it not merely recorded a host of cases already tried and settled but also contained the principles of law upon which judgment might directly be based. Moreover it did more than merely settle cases; it trained minds. It was an affair of thought and argument, of nice precision, and in this respect went beyond the cumbersome compilations that were all the barbarian codes had to offer.

In time a reaction, mainly influenced by the new national spirit, set in against the code, and the swing of popular fashion turned once more in the direction of local custom. Between this and canon law there had already been much affinity, due in part to the fact that lawyers often had to be prepared to plead in both civil and spiritual courts. These lawyers were practically all clerics. The result was that the two kinds of law reacted on one another. Roman law trained the canonist to logic, while canon law gave a bias to the Roman lawyer in favor of regarding the sovereign as an arbitrary legislative power. Papal supremacy thus led on to royal supremacy, for those who accepted papal legislation as beyond appeal were likely to treat as reverently the decisions of any other monarch.

The administrative as well as the legal mind of the time saw grave implications in the mutual influence of the two codes. The imperial ideal had never failed in Europe. Even when the title of emperor seemed in abeyance in the West, and before the pope had revived it to grace the glories of Charlemagne, we find St. Bede in his *Ecclesiastical History* using it freely.

Thus he distinguishes between *imperium* and *regnum*, applying the former only to a ruler who had power over other kings. The Anglo-Saxon kings continued, in their coronation service, phrases that linked their sovereignty with Rome. It may have been for this reason that the pope chose an Englishman (St. Boniface) to anoint and crown Pepin, whose accession represented the final overthrow of the old Merovingian line. The very fact that the Merovingians had been allowed to go on reigning but not ruling suggests a veneration for mere theoretic kingship that in so fierce and rude an age is unexpected. This may have been not Roman so much as barbaric; at least it shows a respect for mere royalty of blood.

Yet from the beginning the royal power and prerogative were held to be limited; in early society the force of custom was so strong that the king was as much bound by it as were his subjects. Usually at the beginning of his reign he promised to observe the laws and customs of his people before he was accepted as "full king," so that he entered upon his office on a distinct understanding that he was not to go beyond what his predecessors had sanctioned. Many monarchs lost their thrones because they underestimated the force of custom. Restrictions from an earlier age might be false and cramping, but to overthrow them immediately was to destroy the basis of the sanctity of government. The monarch in primitive society who attempted too hasty and drastic reforms frequently ended by being himself deposed.

Throughout this period we find that the second check on the power of the king was the rise of a nobility which succeeded in obtaining hereditary offices in the royal household, and ultimately a hold on the crown itself. Thus the house of Pepin, as mayors of the palace, made their position hereditary and secured eventually the crown of the phantom Merovingians, but met, themselves, a similar fate at the hands of the Capetians.

The third check on the royal power was the rise of the estates. However, their influence was not strongly felt until after the period we are now considering. Only in Spain were they important at this time. But the fate of the Christian kingdoms in Spain was too much the sport of war for them to retain their primitive note of democracy, and the premature attempt at representative government could not survive.

Although the king's power was checked and

was to be even more limited, he had many prerogatives that increased the prestige of his royalty. He had some sort of consecration; he was a sanctified person; he was as much "the vicar of God" in his own sphere as was the pope in his. Moreover, besides his sacred character as the personification of his people, he was, on the same principle, their supreme judge. He was not the fountain of justice, for there were remnants everywhere of the tribal courts which had been older than the royal courts. He was, however, the supreme administrator of his people. Except on his own personal territories he exercised this administrative power through officials who were local, like the *comites*, or centralized, like the officers of the household. These office holders all tended to become hereditary and irremovable, and the kings found that their best protection against this situation was to choose their personal administrative court from the clergy.

Administration implies finance and the royal mint with its officials was a natural development. Originally, it is probably safe to say, the exchequer dealt in the main with justice and was a court of fines, so that money came to it principally as the perquisite of justice. But the increasing determination of the king to be the real controller of his people's destiny made larger financial resources imperative for him if he was to interfere effectively and take over what had hitherto been done by war lords, or inaugurate what had hitherto not been done at all. Hence the gradual evolution of the exchequer into what was primarily a centralized treasury. In these earlier days of mediaeval national life the increase of royal power meant the multiplication of royal officials, and the multiplication of officials, stationary or *on-eyre* (the Carolingian *missi dominici*), meant both greater need of money and greater importance attached to local meetings that could raise money. Thus the more extravagant the king, the more he fostered what might become representative government.

VI. This development was no silent evolution, nor was it altogether blundered into by accident. It was part of a general and orderly movement, pushed on alike by needs and by theories. We cannot consider these ages apart from their thinkers and writers who influenced enormously the particular shape that mediaeval life assumed. Of the chief determining personalities, one opens and the other closes our period.

There can be no question that St. Augustine (430) and St. Thomas Aquinas (1225-74) between them molded the thought of the earlier and later Middle Ages. Of these St. Thomas was the more consistent and systematized and St. Augustine the more original and versatile. St. Augustine was of the African shore and lived in the two political centers of the West, Milan and Rome. The influences to which he was subject are clear everywhere in his writings; he is half Eastern or African, and half Roman and of the West.

His political doctrine can be seen in almost all his works, but chiefly in his *City of God*, a rambling disquisition on the church and the empire, on the earthly and the heavenly Jerusalem, on politics, history and religion. He is working out in it not one thesis but a score, so that he follows no one argument nor any particular metaphor. The book has different meanings according to the point the author is trying to prove. Generally we can be sure that he holds the great stoic doctrine of a division between nature and convention, equating it with the Christian doctrine of the fall, believing nature to exist in innocence, and convention to be the remedy discovered by man after the introduction of the mischiefs of sin.

The three great institutions of social life, namely government, private property and slavery, are all defended by St. Augustine as being the inevitable results of the disorder effected by sin. Had men not sinned, these institutions would not have been necessary. Man having sinned, the need for these three became imperative. They are not created by any legislation, for they are presupposed in all codes. Therefore, he argues, they must have been inherent in primitive society and have evolved through experience. While they might never have been discovered solely through abstract thinking, their emergence was inevitable, since without them social life is impossible. If any society discarded them, it would be forced to return to them, since they are the inevitable and divine remedy to pacify and set in order the greedy desires of sinful man. What we would now call communism, or even the academic theory of socialism, would be judged by St. Augustine and all his followers as a possibility only for saints. To be workable, they require "unfallen" nature. Between man and such a memory, said a later mediaeval writer, stands an angel with a flaming sword.

The main contention of St. Augustine is that

over all is the rule of God. This "eternal reason" which creates and gives purpose to every part of creation as well as to creation itself has also been imaged in the being of man and is reflected in his intelligence and will. But the fall disturbed the harmonies of man's nature and troubled the reflection of this eternal reason. Hence sin disordered not merely the emotions and passions in their relationship to the will but the mind also in its relation to the divine law. Hence came the imperfection of man's knowledge, for the reflection of truth was distorted by sin. Revelation helped man to recognize the truths which our now disturbed and ill-balanced reason could not have discovered for itself. Here lay the importance of the "teaching church" for the civil power. It was the business of the church to decide what was morally right and just; and consequently in order to prevent the natural and now fallen reason from false judgments it had a definite jurisdiction, not over the civil power but over its laws and directive administration. It made no laws and had no temporal rule; but it could and should judge laws in order to see if they were just, and it could reprove the temporal ruler who failed in his sworn duty to his subjects or to the church.

It was because St. Augustine placed the purpose of man's creation in the enjoyment of God, and also laid down the principle that both church and state were here to help the achievement of that purpose, that his doctrine of political and social theory led to conflict between the two powers. It is necessary to recognize that the troubles which followed were produced not by any depreciation of the civil power but rather by the assignment to it of a place where its sphere was not only moral but religious. Thus Ambrosiaster (*circa* 390) said of the monarch that he was to be revered on earth as vicar of God (*adoratur in terra quasi Vicarius Dei*). Aquinas spoke, too, of kings as "ministers of divine providence." Once it was settled that the primary object of civil government was to help men toward the accomplishment of their purpose (namely the enjoyment of God), the state was furnished with a pretext for interfering with the church. Investiture and the other topics of controversy showed that opportunities for interference would not be wanting. St. Ambrose had endeavored to forestall this by reminding the Emperor Valentinian that "in matters of faith it is the bishops who sit in judgment over emperors and not emperors

who sit in judgment over bishops." But this was merely a reminder of the older teaching. Church and state had, since the days of Constantine, been held to be separate. So it had been stated in the teachings of the popes and the earliest political writings of the fathers. The idea was implicit in Christianity. A pope like St. Gregory the Great might be a little more tender to the civil power than the strict letter of the law obliged, but only because he believed that the end of the world was imminent. He would do nothing in the chaos caused by the collapse of imperial rule in the West to weaken still further the prestige of Byzantium.

The next centuries of prolific political writing naturally center around the renaissance of culture under Charlemagne. The Carolingian ideals were high; the civil power in this new era was eager to work with and through the church for the betterment of mankind. Both East and West still looked upon themselves as a single unity; the claims of Charlemagne were recognized by the Emperor Nicephorus who saluted him (811) as the Augustus of the West, the successor of that other Caesar whom Diocletian had deliberately created. There is little difference of political theory on this point to be noted in men like Sedulius Scotus (884), Abbot Smaragdus (830), Jonas of Orléans (843), Rabanus Mauras (856), Archbishop Hincmar (882), Hugo de S. Maria (1119), John of Salisbury (1180), and the rest of the writers who came between Gregory I (604) and Innocent III (1216). With some minor peculiarities they maintain for the most part the same attitude to the relationship of church and state, namely the separation of spheres, the spiritual right of the church to judge the laws of the state, the absence of any right on the part of the church to legislate in temporal affairs. Moreover this position is maintained on the principle expounded by St. Augustine, inherited by him from the earlier fathers, and by them derived from the stoics—namely the dual nature of man, his former innocence and his present sinfulness. In his former state man was free and equal and without possessions; since the fall he has needed to be set in a social hierarchy, to be in submission to someone else and to have property of his own. Thus Archbishop Agobard of Lyons (840), for instance, forbids the baptism of the slaves of Jews without the leave of their master, because "by nature all men are equal." So, too, Gregory VII (1087) denounces the civil authority as

the devil, meaning little else by this than that it is a remedy, even a divine remedy, introduced to deal with sinful and therefore rebellious man.

We have henceforward a growing host of writers who discuss the principles of morality in political and social life, since Christendom has grown conscious of itself and has settled down to a state of peace. The great experiment was being made of a polity of Christian people, the principles of whose rule were to be the Ten Commandments and the laws of the church. Our period witnessed its beginnings, crude,

simple and tentative; within a hundred years Aquinas had organized these beginnings into a logical system and given them relationship and a defense. But our period does not pass beyond the era of vigorous originality, of an intense desire to solve in accordance with Christian principles the problems of the new Europe; an era of high hopes and great ideals on the part of pope, bishop, emperor, lawyer, priest and poet, dealing with violent excitable folk who listened but would not obey.

BEDE JARRETT

V

The Growth of Autonomy

I. INTRODUCTORY. To the student of social theory the Middle Ages present a twofold spectacle. On the one hand he sees the attempt made by the church to concentrate and unify the social activities of Christendom in an all-embracing system of thought and action: at the heart of this lies its sacramental doctrine, guiding and directing the believer through his temporal life to eternal felicity; its agents are the hierarchy, its intellectual weapons the theological schools and universities, and its outward appeal is the wonderful and harmonious architectural constructions, the mural decoration, the sculpture, the glass, the smaller, intimate arts that humanize man's existence. On the other hand he is strongly conscious of the immense variety of local life and of the number of self-sufficient institutions; of the rich growth of corporations or quasi-corporations, and the universal prevalence of "liberties" or jurisdictional rights over persons and territory; these seem to exclude the operation of a central power, and rule out the modern idea of a uniform authority extended over a homogeneous national area, which forms the basis of the state. But the impression in its earlier stages, that is, at any rate, during the twelfth and thirteenth centuries, is not one of contradiction. The theory that postulates the unity of European civilization does not demand its sharp unification. The metaphor of the body, so plentifully used by church writers and reaching its fullest articulation in John of Salisbury, represents most closely the mediaeval idea of this organized life, in which sovereignty does not offer itself as a problem in the way it does to the modern mind, since the idea of law as the *fiat* of determinate human will has not yet come to upset the balanced automatism of local institutions.

Social thought began by a full recognition of the organic character of Christendom: then, as unity overreached itself and spelled unified subjection, as the papacy utilized spiritual methods and resources for temporal ends, the reaction against unity set in, and the national centers asserted themselves. If there is any date

assignable to the beginnings of nationalism in Europe, it is the latter part of the thirteenth century, and directly to be connected with the Pope's overstatement of his own position in regard to France. The papacy was not pursuing a phantom, however much it may have overreached itself in the pursuit. In that age spiritual power, to be effective, had to possess a temporal basis, and it was the acquisition of this that led to the conflict of the papacy with the Hohenstaufen emperors and later to its immense fiscal system which alienated much of the loyalty of Europe and substituted business for sanctity. To the territorializing and commercializing of the papal ideal, which the movements of piety within the church could not arrest, political Europe reacted or, it would be more accurate to say, Europe reacted politically; and the new nationalistic tendency was augmented by the spread of Roman, as opposed to Teutonic, ideas of law. The mediaeval notion of the rule of law bowed before the notion of law as the positive command of the prince, and the way was open for despotism and ultimately for the Reformation. That course might have been saved had men in the early fifteenth century found it possible to agree upon an international form of church government, and there were the brightest hopes that the Conciliar Movement might show them the way. But the nationalizing process proved to have gone too far, the financial methods of the papacy to have taken root too deeply, for success to be achieved. Internationally, just as nationally, constitutionalism could not stand the test, on the one hand, of self-interest and, on the other, of exclusive spiritual centralization, and the brilliant evening of the Middle Ages closed in starless night. But the movement was not without results for Europe, after the extreme *étatisme* of the Renaissance had provoked its reaction.

II. THE PRINCIPLE OF AUTONOMY. Let us first examine the forces sustaining that autonomy which, as we said, coexisted and could be reconciled with the universalism of the church. It had its roots in feudalism, with its

essential notions of contract and custom; it was perpetuated in the various forms of association, guilds, partnerships and communes, the rich, spontaneous growth of the high Middle Age; and in certain cases it came to fuller consciousness when, often after conflict, the royal power, in virtue of its growing legislative and administrative capacity, was able to guarantee those associations peaceful intercourse within a more or less organized state. We said "certain cases" because in this respect a great divergence is to be noted among the European countries. England, on the whole, was able to preserve a marked balance between the spheres of central authority and of the local communities and organizations; in France the royal power tended to emphasize its centralizing supremacy (for the story of French national unity is the story of the growth of the royal demesne); in Italy it was the local urban units which in the long run coped not unsuccessfully with papal and imperial centralization alike; in Germany there was notable variation, as the central authority became divided between the electorates; and in the Spanish kingdom class supremacy and the rule of *fuero* seem to have deadened the normal interplay of local and central forces.

Feudalism was a stage in man's political education before he recovered what had been lost in the chaos of the Dark Ages proper, the sixth and seventh centuries: the habit of obedience to public authority. He had lost it, needless to say, because the state itself had been destroyed, and its place taken first by tribal hegemonies and later by lords powerful enough to give protection to their neighborhoods in return for the tribute of obedience. In spite of the revival of political power in the West in the ninth century, and notwithstanding the Carolingian capitularies (soon to become a dead letter), the place of public law continued to be taken by private law and, except in the countries bordering upon the Mediterranean where written codes were still in vogue, customary law prevailed. Political obligation was thus replaced either by tribal allegiance or by the system of contractual agreements between lord and vassals. Soon tenure of land, rather than the circumstances of birth and descent, came to determine the obligations and the status of the individual. Customary codes guaranteed and stabilized his position, just as in earlier times they had guaranteed his place in the tariff of monetary values marked out by the custom of the *werfeld* or blood-price. Thus we must

banish any notion of conscious and direct legislation before the systematic growth of the royal power took place in Europe. Sir Paul Vinogradoff stated the case exactly: "In rudimentary unions, in so-called barbaric tribes, even in feudal societies, rules of conduct are usually established not by direct and general commands, but by the gradual consolidation of opinions and habits. The historical development of law starts with custom." Or again, in another context: "Law had to be sought and discovered in the vast background of social intercourse."

This is the soil—the soil of private and customary law—from which the characteristic institutions of the Middle Ages sprang. They did not come into existence at the behest of any government which formally licensed them, but were due to the principle of economic necessity or of free association for religious or cultural purposes. Often they had to fight for existence, to maintain which they found it needful to create for themselves a clearly defined corporate life, with governing authorities and a customary constitution. Once organized they were recognized as natural and necessary parts of the social order, fulfilling, as they did, functions which today are normally undertaken by the public authority. This notion was extended to classes just as much as to religious or economic associations. Defense was undertaken by the military tenants, prayer for the whole community by the clergy, work by the rent-paying socagers and the unfree natives, commerce by the burgesses. The autonomous political federations of Germany—the military groups under feudal law (*Lehnrechte*), the sergeanties under their special customs (*Dienstrechte*), the rural districts under peasant customs (*Bauernrechte*) and the towns under borough customs (*Stadtrechte*)—reflected this idea of a specialist and at the same time organic society, each part of which, by preserving its own custom and defending its liberties, served the common weal. It is the same in England. The chroniclers speak of a *communitas barnagii* which they regarded as the political class *par excellence*, the only body capable of getting a charter out of King John; the records tell us of the *communitas ville*, the unit that decided the agricultural arrangements. Feudalism might be imposed on a district from above, as in East Anglia at the time of the Norman conquest, the manor might become the unit to which rents and services were paid, but the custom of the manor, which the lord might not infringe,

poked its head through the network of lordship and vindicated the principle of economic organization among the villagers who in their generations had helped to determine it.

III. THE FORMS OF ASSOCIATION. It was town life which gave birth to the richest variety of experiments in self-government or of voluntary associations for religious or industrial purposes. Economically the town cut across the old feudal manorial arrangement by which the scattered village communities sent their goods to the lord's place of consumption. Founded in many cases originally for strategic purposes, it became the center of both marketing and production, although not in the fullest sense until it had vindicated for itself a direct relation with the royal power or got free, when possible, of intermediate overlords whose officials, like those of the king, it succeeded in excluding. The process by which this was effected was a long and complicated one and cannot be described here; whatever its genesis, the commune stood as the sworn association of townsfolk, formed primarily for the purpose of trade, and governed in the north by its mayor and jurats or *probi homines*, in the south of France and in Italy by its consuls and the various assemblies of the citizens. The corporate status achieved by the town differed in a marked degree from the system of private bargains and obligations prevailing without. Vassalage and serfdom were discarded—*die Stadtluft macht frei*. As has been well said, "its walls, personal freedom of denizens, market and civic immunity made the town a detached unit with an incipient political life of its own." As such it might ultimately find representation in a national assembly of estates.

Within it grew up unions for trading and industrial purposes. The earliest associations of citizens were commercial associations, merchant guilds which were in some cases identifiable with the governing authorities of the town, but in the majority of instances were more like chambers of commerce, entry into which was limited to citizens who were holders of burgage tenements within the walls. The merchants of the guild traded collectively, availed themselves of the privileges granted to them collectively, especially that of pleading within their own walls and of free passage along waterways and roads. But the period with which we are dealing had also seen the rise of groups of artisans organized into groups of fellow craftsmen, themselves the makers, employers and vendors

of their own wares. These associations might have come into being partly through physical contiguity in the same suburb or quarter, partly through common religious observances and festivals. They were controlled by the municipalities, which insisted on a standard of quality, on a "just" price to prevent undercutting or undue enhancement, and on sale within certain authorized hours. The guildsmen themselves appointed their "triers" or overseers to supervise the quality of the work, and held the monopoly both of the industry and of the sales within the town. Collective trading, monopoly, fixed standards from which it was an offense to depart, were the three main characteristics of these organizations.

The city, then, as a place of exchange, a distributor or a vendor of the wares made by its own industrial corporations, was the essential trading agent of the great period of the Middle Ages. But not necessarily in isolation. The towns might ally together in a system, such as the famous Hanseatic League, with its own customs, its "counters" or depots (e.g. the steelyard, or the counter at Wisby) outside its own boundaries, and its own courts and guild-halls. Commercial arrangements between one set of towns and another, e.g. between the Low Countries and the Italian littoral, or between the Gascon communes and the English and Flemish seaports, showed a remarkable variety of corporate initiative, which even a prolonged war did not bring to a standstill. Mercantilism had not yet fully made its appearance, and the trading groups, provided that they could get license to pass in and out of foreign countries and safe-conduct within, took their own way unhampered by national considerations. It would not be accurate to state that the thirteenth and fourteenth centuries knew the full meaning of free trade: foreign merchants had often to pay customs on goods, as the English *nova custuma* show; on the other hand the universal prevalence and applicability of merchant law point to something like an international system of trading, and the great fairs of Champagne were in the fullest sense free cosmopolitan centers of exchange.

The fact that urban society was in essence commercial society had a considerable effect upon the movement of social ideas. It meant that the practise of the towns constituted the main practical criticism of the predominant clerical theories of property and money-making. It has been well remarked that it was money

which altered the attitude of the mediaeval mind to property. To minds of the eleventh century wealth lay primarily in the service and suit entailed by land. Now, as money became the new basis of state organization and elaborate royal exchequers were organized throughout Europe and more peaceful habits prevailed, the idea of *service* grew fainter, and land began to be thought of in terms of exact money equivalents, not in terms of conditional services. Thus land was regarded as a thing in itself, as a source of wealth, something that was coming to be owned directly and absolutely. Here urban conditions showed the way. The researches of M. Des Marez in the history of the Flemish communes in the thirteenth century have revealed the movement on the part of an urban patriciate, itself the result of the process of engrossing tenements, buying up houses under conditions permitting of easy sale and thereby accumulating resources of capital for future use. At the same time the early tendency toward capitalism in the easier and more elastic urban environment was breaking through the usury prohibitions of the canonists and challenging the Aristotelian doctrine that a limit to money-making is imposed by the purpose for which money was made. Father Bede Jarrett has spoken of the moral difficulty that confronted mediaeval writers "of making profit-taking in trade fit into the scheme of the gospel." The doctrines of mediaeval theorists have been accepted far too literally as corresponding to established fact. Apart from the practise of the Italian city-states, where there was extreme latitude, the papal curia at the beginning of the fourteenth century was itself no mean profiteer, and never above taking money from its bankers at no mean rates of interest.

But mediaeval communities were by no means exclusively commercial: they were religious and governmental, too. The development of the indulgence system by the church led to the formation of various fraternities, often called after the saint to whose shrine indulgence-bringing pilgrimages were made. The participants were admitted to profit by the merits their saint had acquired, and later the fraternity system developed along the lines of provident, burial and intercessional societies. In the institution of monasticism, the most coherent and powerful of the forms of association in the Middle Ages, the religious houses were in a

very real sense communities, although the degree of self-government varied according to the type of religious order. It has been argued with some plausibility that they exemplified the nearest approach to communism seen in the Middle Ages; for the original purpose of the Benedictine rule was to found independent families of religious, whose individual members lived in poverty which, together with chastity and strict obedience to the superior and the rule, was considered necessary for the imitation of Christ. It is impossible to enumerate here even a fraction of the self-governing charitable institutions of the church. But if we pass to secular society outside the towns we shall not be able to withhold the notion of community either from the franchises of great lords or from the counties of mediaeval England. The "liberty" (public jurisdiction in private hands) was a unit of government that ran itself, with its own officials responsible to their lord, who in turn was responsible for its conduct to the royal power, although the extent to which that responsibility was realized varied very greatly in the different countries of Europe. Here the nexus of union was service to the center of jurisdiction, the suit to the lord's court. Suit to the common center was likewise the bond of that most real and effective of governmental communities, the English shire, quickly called into self-realization by the work put upon it in the way of taxation and justice by the English monarch, and finding methods of representation through the very machinery that royal inquests of all kinds had made normal and necessary.

The legal status of these most variegated communities differed surprisingly. It is extremely difficult to know how far we may predicate corporateness, for example, of a fraternity, to what extent the community of the shire, embodied in the county court, had the legal personality possessed by an abbot and convent. But one generalization may be attempted. The mediaeval king might confiscate the temporalities of a convent, he might take a town or a liberty "into his own hand"; but he would not permanently alter their status or, unless they belonged to an enemy power or had entirely outlived their original religious purpose, suppress them. They were part of the social order, their positions were guaranteed by written or unwritten custom which it was his duty to preserve. The coronation oath which he took was the oath to defend this

highly articulated order, to forbid rapine and the encroachment of one section upon another, or of individuals upon any one of them. This was involved in the idea of the rule of law, the most powerful and lasting contribution of the Middle Ages to modern political thought.

To the mediaeval theorist of the thirteenth century the conception of the monarch as the source of law and superior to all law was, as we observed, alien. When Bracton said that the king was under God and the law, he was saying something that all western Europe could understand; for to holders of this view law was the bond uniting the various parts of the body politic, preserving communities and individuals alike in their different estates. The king's court was the body which was the guardian of this cohesive system of rights, the source of appeal if any were infringed, and the collective arbitrator when doubtful issues arose. On this point the weighty judgment of Dr. Carlyle should be heard in full: "It is only when we take account of this fundamental principle of mediaeval constitutional law that we can properly understand the real significance of that famous clause of Magna Charta in which it is laid down that no free man should be imprisoned or disseized or destroyed or even attacked without the legal judgment of his peers or the law of the land. We are not here concerned with the detailed interpretation of all the phrases of the famous passage. . . . It is enough for us to observe that it is not an isolated attempt to establish some new principle of the law and the constitution, but that it was in its most essential principle nothing but a restatement of the fundamental principle of the feudal and constitutional system of the Middle Ages; that whatever authority was possessed by the lord or prince, it was limited and controlled by the law, and that this law had as its guardian a properly constituted court, and that this applied to the king or emperor as much as to any lesser lord."

The idea of the limitation of political power, as understood by the British and American peoples, derives in the first instance from the doctrine and application of the rule of law in mediaeval English government, and has its rise in the feudal guarantee of rights and the determination, put more than once into practise, to insist upon it. That guarantee was given a contractual form, for contract was the essence of feudalism. In the insistence upon the contract, first the baronage and then the organized com-

munities of the land in Parliament made their great contribution to the destruction of absolutism. But neither the royal power nor the communities were wholly or permanently successful, and this equilibrium, which is found also in subsequent constitutional history, serves to explain why in England today monarchy coexists with democracy.

IV. THE UNIVERSAL SYSTEM. We have seen how the feudal organization of society with its notions of contract and custom insured the status of the community life of Europe and held at bay the idea, ultimately to triumph, that the will of the prince has the force of law. From the diversity of group life, so guaranteed, we must turn to the unified system of administration and theory that prevailed in spiritual and temporal matters during the thirteenth and the following two centuries.

It must be said at once that the unity of Christendom was a fact only in a very limited sense. What actually existed under Alexander III and the greatest of his successors, Innocent III, Gregory IX and Innocent IV, was a central court of church law for the whole of Europe, a highly centralized spiritual administration that never ceased to develop, and a more or less complete enforcement of canonical obedience to superiors and so ultimately to the papacy. In temporal matters there was the Holy Roman Empire, in theory universal, in practise confined to the Germanic kingdoms and Italy, never embracing France, England, Spain or the Balkans. If we look more closely we shall see that only at a comparatively few periods was imperial supremacy unchallenged, even in Germany and Italy. The pope and the emperor were in theory the two ruling officials of united Christendom: in practise they had been and were continually fighting each other, and at intervals the internal structure of their own monarchies was shaken with the gravest dangers. Yet there was unity of Christendom through a powerful threefold nexus: the sacraments of the church, canon law, the Latin tongue. Furthermore before the end of the thirteenth century the papacy had been able to mobilize the western nations in the crusade, the symbol of European unity against the infidel in the East. Thus unity, administrative, literary and militant, indeed existed; and churchmen maintained the ideal of a Christendom multiple in function, one in spirit, continually floating, before men's eyes. Nor should we forget the art

which in the *tympana* of the doors, in the sculpture and painting of sacred buildings, gave illustration to that ideal, exemplifying the passage of man through the present life, under the church's guidance, to his eternal felicity or, apart from the church, to his eternal damnation.

We cannot but be struck by the contrast between the early Christian communities and the Catholic church of the twelfth, thirteenth and fourteenth centuries. As Troeltsch has pointed out, the peasants and fishermen who gathered round Christ and the Apostles were not official rulers nor learned doctors, but derived their leadership from religious conviction and prophetic spirit; on the other hand the church of the central Middle Ages had developed a powerful and complex hierarchy, "armed with scientific doctrine and superior technique." The power of the hierarchy, manifested in many characteristic ordinances, and the obedience it claimed were derived from its position as shepherd of the Christian flock. Care of the sheep carried with it the authority over the believer. But in process of time and with the development of doctrine this position had come to rest not merely upon the evangelical command but upon the sacramental duties of the priesthood. To all alike the hope of salvation was vouchsafed by the miraculous grace of God, and to that miraculous grace Christian thinkers traced the reversal of the general condemnation of mankind through the act of atonement—the incarnation, suffering and death of Christ. The efficacy of the reversal for each individual depends, however, upon the personal reconciliation and regeneration; and, as Troeltsch pointed out, the miracle of grace is prolonged in the shape of the mystic life of the church, which unites the living and the dead, and helps all struggling for salvation against sin in this life. Dante expresses this idea of the mystic unity and miraculous mediation of the church in the beautiful version of the Lord's Prayer put into the mouths of the souls in purgatory waiting for salvation (it has the ring of Virgil's "*tendebantque manus ripae ulterioris amore*"):

Vegna ver noi la pace del tuo regno
 Chè noi ad essa non potem da noi
 S'ella non vien, con tutto nostro ingegno.
 Come del suo voler gli angeli tuoi
 Fan sacrificio a te, cantando Osanna,
 Così facciano gli uomini de' suoi.

The doctrine of the church as, again in

Troeltsch's words, the "sacramental institution for salvation," is the corner stone of Catholicism and its concrete development. Grace, the sole means to salvation, is conferred by the seven sacraments, covering the whole range of man's spiritual requirements. The church's object, her *raison d'être* itself, is to convey these sacraments to men.

The mystic life demands an organization. Von Hügel in his address on the essentials of Catholicism has remarked that Catholicism is essentially organic. The social body it aims at building up is constituted by the several groups of men, down to the individual souls; to those groups and individuals "it gives their characteristic functions and delicate irreplaceable reactions." The organism must have a directing soul which moves the various members. In the mystic body of the church the direction comes from the head, Christ; but the visible acts of the organism depend on constituted authority, and this authority is the papacy. It would be impossible here to give any account of the gradual development of papal power in the church: we need merely call to witness the monarchical tendency of political theory in the later Middle Ages, due to what Vinogradoff has termed "the historical necessity of concentration amid the centrifugal movement of a society broken up into a quantity of local units and composed of a multitude of heterogeneous elements." That concentration arose first from the challenge to Rome's authority offered by the Donatists and by the Arian revival in Visigothic times; it continued in the struggle to claim church property from lay hands, which underlies the various Donations, true or fictitious, and the Forged Decretals; it was sharpened by the opposition of the Eastern Empire; it was developed in the struggle for tithe, and then in the great movement for the defeudalization of the church that culminated in Gregory VII; it was augmented by Innocent III's schemes for clericalizing society, for engendering in all believers the ecclesiastical point of view, and after the life and death struggle with the Hohenstaufen it reached a commercial climax at Avignon.

The legal weapon that held the centrifugal tendencies at bay was the canon law. Maitland described this system in unforgettable words: "It was a wonderful system. The whole of western Europe was subject to the jurisdiction of one tribunal of last resort, the Roman curia. Appeals to it were encouraged by all manner of

means, appeals at almost every stage of almost every proceeding. But the pope was far more than the president of a court of appeal. Very frequently the courts Christian which did justice in England were courts which were acting under his supervision and carrying out his written instructions."

By the thirteenth century the canons had provided the system of organization to the church. The laity was reduced to a condition of obedience: the life and position of the hierarchy of clerks were regulated in every detail, and the papacy had begun to intervene in the political relations of one ruler with another through claiming judgment in cases of sin. Innocent III expressly kept clear of questions of feudal law; but on moral questions the ecclesiastical tribunal might step in and judge the recalcitrant prince. Thus in both spiritual and moral affairs, in all matters relating to the sacramental life of the church, the church's unified and centralized legal activity claimed and did in fact exercise supreme competence with the concurrence of society. And just as the church in her world wide claims and administration was the political legatee of the single world wide empire of Rome, so in her language she maintained the unity of this legacy, and developed in it the wonderful flexibility of a still living tongue, both in her hymns and her poetry which called on men to look with expectation to the one republic on high:

Bone pastor, panis vere
Jesu, nostri miserere.
Tu nos pasce, nos tuere,
Tu nos bona fac videre
In terra viventium.
Tu qui cuncta scis et vales,
Qui nos pascis hic mortales,
Tuos ibi commensales
Coheredes et sodales
Fac sanctorum civium.

The writer of these simple lines of immediate appeal was the author of the most profound philosophical treatise of the Middle Ages.

In a rough age unity of the faith could not be procured by spiritual weapons alone, nor could breaches of that unity be punished solely by the normal penalties of interdict or excommunication. Churchmen had to make up their minds upon the problem of force, whether, when and how it was to be resisted or used. It was part of the church's duty to restrain the love of mere violence and the bestiality which disgraced the life of the military classes; and restrain it

she partly did by instilling into their minds the principles of chivalry, or by diverting the emotionally awakened West to the defense of the holy places in the crusades, or by leading the forces of the orthodox against those tainted with heresy. The ceremony of conferring knighthood, the military orders which held the points won in Palestine after the crusades were over, and the Holy Office of the Inquisition were the legacies of the solutions adopted in these three cases. Chivalry was the most characteristic and significant, because it was the most normal, of her methods. The various mediaeval statements of a knight's duty which have come down to us are strongly ecclesiastical. The knight must hear Mass daily; he must die for the faith, if need be, must protect widows and orphans, not make war without good reason, not espouse unjust causes; he must bear himself humbly in all things, and it is his duty to preserve the goods of his tenants and do nothing contrary to the interests of his suzerain. Fidelity to the suzerain was emphasized as a guarantee of social stability in an age when the peace of society depended on the keeping of feudal engagements. The unity of Christendom in the faith and the preservation of the peace were the aims of the church in society. War she could not prevent, but she could harness and moderate it. It cannot be said that she entirely failed in these tasks—at any rate until the fourteenth century. And so deeply did the idea of unity strike that even when it no longer could or did exist, it formed the mainspring of the noblest ideal of a united Christendom ever propounded by political thought—the *De monarchia* of Dante. This tractate is all the more striking because it was written by one who had no sympathy with clerical government, by a "white" Guelf who had suffered the loss of all through the machinations of Boniface VIII in league with Florentine commercial interests. It is a great plea for universal empire, the only condition of peace, since a unity of discordant wills can be secured only by the governing will of a single person. Dante argues that the proper function of the human race, for which God by His art has created it, is to bring into play the whole capacity of the possible intellect for contemplation and for action, and that this can only be achieved when the one guiding power, the emperor, by his rule of justice spreads peace and creates the opportunities for this intellectualized activity. His argument that *this empire* is the Holy Roman Empire, the prolongation of

the divinely willed Roman Empire, is not so important for our purpose as his demonstration, carried out by pointing to the end of the human race, of the necessity for world wide unity, and his conception of the emperor as a permanent source of international justice and an impartial tribunal of international arbitration.

V. THE SCHOLASTIC PHILOSOPHY AND ITS VIEW OF SOCIETY. The central period of the Middle Ages is the period of the *Summa*: that is, of the attempt to synthesize all knowledge and speculation in a single body of Christian philosophy. The *sapientia christiana*, which this was called, is the intellectual form of the legal and administrative control which the church attempted to exercise over the spiritual life of Christendom. It included the twin spheres of faith and reason, dissociated by St. Thomas Aquinas who, following his teacher Albertus Magnus of Cologne, broke the spell of the Augustinian theories. The emphasis which he laid upon free will undermined the Augustinian idea of predestination, the real principle of division between the two cities in the *De civitate Dei*, while his theory of knowledge aided in developing and enriching the notion of human personality to an extent impossible while the intuitionist doctrine of knowledge held the field. The philosophy of St. Thomas, besides bringing to its mediaeval culmination the notion of the *person* as an independent center of thought and action, made to social theory contributions along two very important lines: on the model of Aristotle it took as its governing principle the notion of *purpose* in the world-process; and it gave prominence to the idea of *law* as sustaining both the physical cosmos and human society in its various groupings and units—the philosophical counterpart of the idea of custom noted above.

St. Thomas took over Aristotle's conception of nature and regarded it as the agent of God. With Aristotle he asks, in his *De regimine principum*, what is the purpose of the state and, more widely still, of society as a whole; with Aristotle he concludes that it is the virtuous life—but that is not enough: "since the virtuous man is also determined to a further end, the purpose of society is not merely that man should live virtuously, but that by virtue he should come to the enjoyment of God." Now if people could achieve this end by natural capacities alone, it would be the duty of kings to direct them to it; but the fruition of God, a mystical

ideal, cannot be achieved under temporal direction: it belongs to divine government. Thus "the administration of this Kingdom has been committed not to the Kings of this world, but to priests, in order that the spiritual should be distinct from the temporal; and so to the supreme Pontiff, the representative of Christ." The method of St. Thomas is clear. The character of the supreme directing authority of society depends upon the purpose for which society exists; and because that end was a divine end, logically the government of this world should be a theocracy. It was open, as we have pointed out elsewhere, to any thinker after St. Thomas to use the Thomist method of relating social activities to their ends, but to hold that the purpose of society was not an otherworldly one; to deny, in fact, the transcendental view of the objective of human life, and to go no further than to suppose that the end was temporal happiness or smooth administrative efficiency.

The idea of law in St. Thomas is the complement of his theocratic doctrine. Blessedness, the divine end of man, is achieved through life lived justly in a society in which law governs and directs. For St. Thomas law is not first and foremost the determinate command of some human superior, but "a rule or measure of actions," dictated by reason, aiming at the highest good, not at the profit of individuals. It reflects the *ratio*, the reason (or, better, "reasonableness") in which both ruler and ruled participate, a reason which, just like the individual purposes in man, serves and is set in motion by the "highest reason existing in God." Human law must be in accord with these natural or reasonable principles: it need not be dictated by nature, for obviously *jus civile*, positive or conventional law, is not, but it must not be opposed by nature. "Every human law has as its condition of being a law that it shall be derived from a law of nature. . . . It is of the essence of a human law that it should be derived from the law of nature." Thus just as the purpose of each individual life serves a supreme purpose, so individual laws serve and "respond" to a supreme law; and the doctrine of purpose which we noted above is applied to the juridical sphere in such a way as to provide a criterion for the positive enactments of the prince. That the prince should observe the law constituted no lack of sovereignty for him, if we accept this definition of law. Thus political philosophy came to the support of constitutionalism.

VI. THE REACTION AGAINST THE THEORIES OF THE CHURCH. Since the death of Innocent decretalists (the commentators on the Decretals of Gregory ix) had never ceased to extend and exaggerate his statement of the papal claims. It was they and the papacy by its temporal demands and the fiscal measures undertaken to satisfy them that led the secular power, Philip iv of France in particular, to challenge the doctrine that the papacy possessed both spiritual and temporal swords and the declaration of Boniface viii to the effect that the subjection of every human nature to the supreme pontiff is necessary to salvation. The lay argument, in the mouth of John of Paris (1302) for instance, is put in a feudal form. The royal power is in no sense derived from the papal, but from God. The king of France holds from none but God alone. The author of the *Disputatio inter clericum et militem* (about 1296) claimed for the king of France legislative power similar to that of the emperor. "The author," remarks Dr. Carlyle, "is clearly thinking of the legislative power of the French king in terms of the position of the emperor in Roman jurisprudence, and while he formally allows for the possibility of the king legislating with the advice of his *proceres* (nobles) he does not think of this as essential." The Roman influence is significant, for in other writers it led to a more far-reaching thesis: the denial of the theory of law adumbrated above (not a denial that law should be reasonable, but a denial that any man or body of men have the right to proclaim the prince's law to be unreasonable) and an attempt to limit it to purely temporal origins and circumstances. The civilians of Bologna, following their Roman models, derived it not from custom or nature but from the definite human will of the ruler, on whom the people had conferred its legislative power. The remarkable theorist, Aegidius Colonna, would go further to argue that it is better to be governed by the prince than by the law.

The most powerful theoretical attack on the papal claims came from a Paduan physician and a French Aristotelian, Marsilius of Padua and Jean of Jandun. The occasion was the struggle of the papacy against the Emperor Lewis of Bavaria, the ally of the Angevin Robert of Naples and the firm opponent of the Ghibelline leaders in Italy; and it is significant that the authors, shortly after writing their book, betook themselves to the court of Lewis

at Nuremberg, and that Marsilius followed the emperor to Rome, where he attempted to put some of its doctrines into practise. Marsilius had seen much of ecclesiastical interference in northern Italy, and without doubt the condition of his native Lombardy chiefly moved him to write the book. In order to demolish the theory of the papal *plenitudo potestatis* he had to prove two revolutionary theses: he had to show that no special divine revelation created the papal supremacy and ecclesiastical jurisdiction, and that the very nature of the state excluded their operation. He had therefore to discuss the nature of the state and to analyze ecclesiastical government. The purpose of the state he defines in the words of Aristotle: it is a perfect, self-sufficing community aiming at the good life—but in this world only. It contains various orders and groups, among them the priesthood, the *pars sacerdotalis*; but the business of the priest is to administer the sacraments and to prepare men for the future life, not to take part in the politics of the present. That social peace may be secured it is absolutely essential that the secular power which governs should be supreme: and this power is the assembly of adult citizens, the *legislator*, which in matters of administration is represented by a *pars principans*, the executive body, elected by the *legislator*, whose authority must be final and absolute, unique and undivided. Marsilius will not allow the priesthood to have any coercive jurisdiction. His analysis of ecclesiastical government confines the functions of the priest to the sacrament of penance and the celebration of the Eucharist. Excommunication, if inflicted, can only be so by the local assembly (which, being Christian, he terms the *legislator humanus fidelis*). The clergy must possess no property but, like the Roman priesthood, be provided for by the state whose servants they are, and elected by the Christian citizen assembly. The papacy is not a creation of divine revelation: it is an administrative episcopate, and all bishops are indifferently successors of the apostles in general.

This frankly Erastian treatise, almost immediately condemned by the papacy (and what wonder?), is remarkable for its absence of internationalism, its lack of arguments for a world wide empire such as Dante had foreshadowed. Its hard realism breathes the spirit of a commercial city which had had enough of the interference of a universal power. But Marsilius does provide some international machinery for cases where there are differences of interpre-

tation in the church over scripture or dogma. Then a general council must be summoned, the representatives being clerks and laymen elected by the *legislatores humani fideles*, the Christian citizen assemblies. The idea of a general council was by no means new: such a body under Alexander III (in 1179) and Innocent III (in 1215) in its decrees had registered papal policy with the support of the church; yet the council now thought of was not to be held at the behest or for the assistance of the supreme pontiff but for the decision of difficult matters in the church, where the papacy could not avail. In this sense and with this intention there had been an anticipation in the treatise on Conciliar government by William Durandus in the thirteenth century. But the demand for such heroic remedies was not loudly heard until constitutional doctrine arose to meet a situation in the church unparalleled for the length of its duration and the evil of its consequences: the Great Schism of 1378-1409.

The period of the Avignonese captivity in the papacy had been marked by fiscal reforms and experiments on a large scale. By leaving Rome (which, because of the quarrels of the great families, would have been necessary in any case) the popes lost large sources of revenue; but apart from this there were petty wars in Italy to finance, the patrimony to protect, a residence at Avignon to be constructed; and to meet the needs of a greatly increased budget they had to strengthen the financial machinery at the expense of the local churches. This was done principally by increased taxation of all kinds, and by a system of collation to benefices which reserved more and more classes of livings and cures to the papacy and annoyed ordinary collators, especially the national monarchs. The curia was reorganized and centralization in the church reached its climax. This concentration had the effect of arresting the measured flow of canonical obedience through the grades of the hierarchy; it disturbed the ideal symmetry of the church by undermining the authority of prelates. The lack of discipline in the pre-Tridentine church is the direct result of the numbing of diocesan life and activity or, to change the metaphor, of Rome's short-circuiting of her subjects. The great protest against this suppression of local life came in the constitutional outbreak which we know as the Conciliar Movement. By character this was early mediaeval through and through in its

attempt to foster local church life through representation, to get back once more to the graded type of society, to call into active being the diocesan communities undermined by papal collation to benefices and the multitude of papal dispensations and organizations. This, however, did not stand first on the Conciliar program. Reform came after unity, the unity that was destroyed by the competition of Italian and French candidates for the papacy; and when in the Council of Constance unity had formally been achieved, that body was too much divided along the line of national animosities and peculiarities, and too much occupied with the suppression of heresy and with irrelevant administrative matters, to deal seriously with reform. But the rock on which the *causa reformationis*, which was in all good men's hearts, really foundered was the old problem of finance—how to recompense the papacy, which needed every penny it could get now that it had returned to take up its Roman patrimony and inheritance, for the loss of taxes and collations which the reformers demanded that it should undergo, but which had constituted the main source of its revenue during the Avignonese time.

VII. CONCILIAR THEORY. The theory underlying the mass of Conciliar treatises finds its greatest exponents in Jean Charlier de Gerson, chancellor of the University of Paris, and, at the time of the Council of Basel, in Nicholas of Cues, the German philosopher, reformer and later bishop of Brixen. Both believed that the constitutional doctrine of representation in secular politics could be applied to the government of the church: both held that the representative body in the church was the general council. Gerson took his stand on the doctrine of *epikeia*, or the equitable, in place of the rigid, interpretation of law. The schism presented an emergency unprovided for in the law of the church. At all costs the views of extreme canonists had to be overridden and the only remedy tried which was then feasible (1409). In his reaction against the rigid legalism that would permit of a general council being summoned only if the pope gave his assent, Gerson was at one with the spirit of his time, which was increasingly in revolt against the rigidity of ecclesiastical institutions. Cusanus went further than Gerson to argue, rather like Marsilius, that the papacy is an administrative office alone, with no power to veto (as Eugenius

iv did) a representative synod of Christendom. His argument in the famous *De concordantia catholica* rests upon a fourfold foundation: that the character of the papacy is purely administrative; that all power, spiritual as much as temporal, is dependent on the consent of the whole body over which it is exercised; that such consent is conveyed through representatives; and that the representatives of the whole body, in this instance the church, are the council. This doctrine of consent conveyed through representation had, for the papacy, an ugly democratic connotation; and if the system of voting by nations in the Council of Constance had brought national animosities to the fore, the large numbers of lower clergy and intellectuals (doctors) introduced through representation among the select higher few presented at Basel a most unwelcome feature to the curial mind. The movement as a whole failed, though it registered at Constance the famous decree that the council was superior to the pope and should meet to settle the needs of the church at stated intervals. But even if the papacy emerged from its ordeal strengthened, narrowed and still more centralized, the constitutional doctrines of consent and representation were generalized throughout Europe, and were ready to be used in later times when the excesses of national monarchs produced reaction.

It is interesting and instructive to find Cosanus still cherishing a belief in a united Christendom. It is characteristic of the mediaeval mind that refuses to be disturbed by the discrepancy between idea and fact. For the facts in the middle of the fifteenth century were very different. In Italy communal government had faded into the regime of the signory, in which a single family often had a controlling voice; democracy had passed to oligarchy, and oligarchy was now melting into tyranny. In France Louis XI was behaving as a typical Renaissance despot, centralizing, subduing the fiefs, intriguing against his more mediaeval neighbor Burgundy; Germany was a conglomeration of almost independent electoral and ecclesiastical principalities, their rights sanctioned by the Golden Bull of Charles IV; and in England the house of Tudor, soon to succeed, was ere long to establish the principles of the new monarchy. Everywhere the promise of constitutionalism was failing before despotic control, and the unity of Europe and international government through representatives were no more than a dream. But that vision, which men have recurrently tried to turn into reality, is one of the most permanent legacies of the Middle Ages and, with the true dreams, may prove to have come through the gate of horn.

E. F. JACOB

VI

Renaissance and Reformation

I. In respect of the social sciences, as of all other spheres of knowledge, the keynote of the Middle Ages throughout Christendom had been submission to authority. This submission to authority was the intellectual counterpart to that obedience to authority which had been the dominant principle in every department of mediaeval activity. And the authority which both determined conduct and prescribed creeds was that of the Catholic church. It was the church that fixed the canons of ethics, declared the nature and limit of the Christian man's duty to his neighbor, established and maintained the standards of right and wrong. The church, too, claimed the realm of economics as its own, and not only announced pontifically the conditions under which commerce should be conducted and industry carried on, but also formulated definitively the principles that should decide such questions as whether or not a wage was just, a price equitable or a payment for the use of money in accordance with the Levitical law. Law, moreover, was a prime concern of the ecclesiastical authority. The customs of the nations, the enactments of their rulers and even the venerable civil law of Rome were all inferior in obligation to the canon law based on the divine revelation and developed by the sacred tribunals of the church. As for politics, just as the papal curia in its great days claimed to exercise sovereign power over all Christian kings and princes, so did the doctors of the church formulate the prevailing theory of the state, basing it on the Bible and supplementing the Bible with whatever seemed to them relevant and congruous in the systems of Aristotle, the stoics and the Roman jurists.

The prime characteristic of the period of the Renaissance, on the other hand, was revolt against authority. The emancipated and lawless mind of man began to question the dicta of its ecclesiastical tutors, first, of course, in their own proper sphere of religion, and then, as a consequence, in the sphere of the social sciences over which they had exercised suzerainty. It began to examine the foundations of ethics; to discuss on rationalistic lines the principles of

economics; to analyze critically the nature of law, and weigh the competing claims of the *jus divinum*, *jus naturale*, *jus gentium* and *jus civile*; to develop a political theory which, divorced from religion and free from entanglement with morality, had direct relation to the art of government as practised by the tyrants of the world of practical affairs.

To examine in detail the causes that led to this intellectual liberation does not fall within the scope of this section. They must, however, be indicated briefly; for, unless they are borne in mind, the nature of both the Renaissance and the Reformation will be misunderstood. If we wish to express these causes in impersonal terms we may say that primarily they were the influences emanating from Asia, near and far. If we wish to express them in terms of specific movements we may say that they were the consequences of the crusades and of the Mongol invasions. If we prefer to stress the power of personality in history we may say, without undue exaggeration, that the two main authors of the Renaissance and the Reformation in western Europe were Mohammed and Genghis Khan.

The way for the diffusion of the liberating light of Asia had without doubt been prepared. The barbarians who constituted the peoples of western Christendom had always been rebellious children of the church; although until the time of the crusades their rebellion had been moral and not intellectual. They, in their natural naughtiness and ingrained independence, had resisted the restraining hand of the priesthood, and had all too frequently refused to live up to the lofty ethical standard erected by the saints. Excommunication, interdicts, bulls of deposition—all the weapons of the spiritual armory of the papacy—had been necessary to reduce the sinful obstinacy of the early mediaeval superman. It was, indeed, to no small extent just because the church could not enforce decency of behavior upon the organized brigandage of Europe that she had the happy inspiration to divert and sanctify their predatory and sanguinary passions by directing them to

the recovery of the Holy Land from the infidel.

The crusades, which form the real dividing line of the Middle Ages, had many and far-reaching results. The only one among them, however, that we have to note is this: that they brought the military multitudes of the West into contact with an oriental civilization immeasurably older and finer than their own, and made them conversant with a new world of institutions and ideas. Not a few of the crusaders renounced their former faith, adopted that of Islam and remained permanently as denizens of the East. Many of those who returned to their ancestral homes and retained their allegiance to Christianity came back with an intellectual outlook ineffably enlarged and with an unquenchable tendency to question established creeds. The influence of Asia was manifest in most of the late mediaeval heresies. And the influence of Mohammedan Asia reached Europe not only along the routes of the armies, the ways of the pilgrims and the roads of the merchants who made the Holy Land or Egypt their objective. In two other regions the Crescent and the Cross were in contact for several centuries, a contact, moreover, that was by no means generally hostile. In Sicily, on the one hand, Saracen and Norman—not to mention Greek and Jew—lived side by side in a peaceful polity which fostered the generation of a universal skepticism and the rise of an intensely rationalistic science. In Spain, on the other hand, the Moorish universities became the headquarters of a culture that was based on that of ancient Greece, as transmitted and transmuted through Egyptian, Syrian, Jewish and Arabic channels. Inquisitive Christians, such as Gerbert (later Pope Sylvester II), did not hesitate to risk the salvation of their immortal souls in their desire to learn the mysteries, unknown in the schools of the church, of the higher mathematics and physics, of chemistry and metallurgy and, above all, of the Aristotelian logic and metaphysics. Thus the lore of the Orient quickened the western mind, making it pregnant with new ideas.

The influence of Genghis Khan and of the Mongol invasions of Europe was different in kind. The outstanding fact to be borne in mind is that the empire established by Genghis and maintained by his two successors in the thirteenth century extended from the seaboard of the Pacific in the east to the shores of the Black Sea in the west. Its roads and rivers, admirably patrolled and provided with excellent

hostelries and appropriate vehicles, brought together in mutually profitable union the long sundered civilizations of China and Rome. Now while Rome had gone one way, transforming itself from an empire into a church and developing a culture based upon a creed, China had gone a totally different way, devoting all its talents, in peaceful seclusion, to the perfecting of a culture based upon material comfort. Thus when Rome and China renewed contact in the thirteenth century each was able to contribute much to the other. The great Kublai Khan (A.D. 1260-94) imported Christian missionaries to Peking in order that his people might learn something respecting that spiritual world with which the West had become so conversant. In return his people were able to familiarize the backward denizens of Europe with such powerful agents of progress as the printing press, the mariners' compass and gunpowder.

These three things in particular—printing press, gunpowder and compass—were the material causes of the Renaissance. They brought the mediaeval system to an end. First, the printing press cheaply and easily spread knowledge broadcast among the laity, and broke down that monopoly of learning which the estate of the clergy had enjoyed for a thousand years. Secondly, gunpowder completed the work that had been begun by the bow and the pike; that is to say, it placed weapons of power and precision in the hands of the masses of the third estate, and so destroyed the monopoly of military efficiency which the estate of the European chivalry had enjoyed from the days of the battle of Tours, if not from that of the battle of Adrianople. The armor of the feudal knight became merely an interesting relic of antiquity; while the castle of the noble (a sheer death trap in the days of artillery) was converted into a museum in which to exhibit it. Finally the mariners' compass—especially when supplemented by the quadrant and the chronometer, which were perfected about the same date—made possible for the first time continuous and systematic voyages on the great ocean. Thus it became feasible in the fifteenth century to embark on distant expeditions, and to test those startling ideas of the classical geographers (whose works were early put into print) to the effect that the earth was round and not flat, and that consequently seamen sailing westward across the Atlantic would not reach the perilous margin of the world but

would within reasonable time attain the friendly harbors of India and Cathay.

II. The Renaissance was a composite movement. The outcome of the quickening intercourse of Europe and Asia at the close of the Middle Ages, it displayed many of the characteristics of new and exuberant life. It was, in the first place, the "rebirth of the human spirit"—the resurrection of the mind of man from an intellectual tomb—after a millennium of death and putrefaction. Not that the mediaeval world had failed to make invaluable contributions to the structure of modern civilization. It had made many such contributions, as the preceding section has shown; but they were not intellectual contributions. They were religious, ethical, social and political contributions; not additions to knowledge. For the mind of mediaeval man was entombed, and his spirit wandered ghostlike amid sepulchral superstitions. Such knowledge as he supposed he had acquired was knowledge of a visionary universe that had no existence outside the realm of his own imagination—a realm peopled by fairies and goblins, angels and devils. Science was impossible in a world whose phenomena were regarded as the consequences of incessant and capricious interference on the part of supernatural beings.

That brings us to the second outstanding feature of the Renaissance, viz. the dawn of modern science. The fourteenth and fifteenth centuries were marked by a rapid waning of the sense of the miraculous, and by a corresponding swift increase in the consciousness of the existence of unvarying law. Men began instinctively to seek for rational explanations of events—such as eclipses and earthquakes—which their ancestors had without hesitation ascribed to divine or diabolic interventions. And it was especially in the impressive realm of astronomy that science made its first great conquests and established the evidence of the reign of law. Among astronomical discoveries of the Renaissance era none was equal in sociological importance to that of Copernicus (1473-1543), viz. that the sun is the center of our planetary system and that the earth moves round it once a year. It was a discovery—or rediscovery of a truth known to Aristarchus in the third century B.C.—that was sociologically important for two reasons. First, it shook to its very foundations the mediaeval theological system which was based, beyond possibility of reconstruction,

upon the Ptolemaic principle of a geocentric universe. Secondly, it compelled the thoughtful to contemplate the earth and all human affairs in a new light and in an infinitely reduced perspective. The world shrank to a point in limitless space; the bustle of man's business became inaudible in the immeasurable silences; humanity at length displayed itself in its proper insignificance.

The growth of science and the spread of rationalism constituted in effect a return to the Greek view of life. It was a view in which joy was the most prominent feature, and self-realization the dominant ideal. It contrasted sharply with the mediaeval view, in which the sense of sin filled the scene and asceticism set the standard of virtue. This return to the Greek view was immensely furthered and fostered by that "humanistic" revival which was the third conspicuous feature of the Renaissance. The gradual infiltration of Byzantine copies of the ancient Hellenic classics into Europe by way of south Italy; the renewed study of the Greek language in the academies of Naples, Rome, Florence, Milan and Venice; the printing of the works of Plato and Aristotle, Homer and Hesiod, Aeschylus and Euripides—these were the things that helped to open men's minds, to give rise to crucial questionings, to prepare the way for the reception of science. It was this neopagan outlook upon man, upon nature, and upon God, too, that gave rise to that marvelous manifestation of brilliant art and splendid literature which makes the Renaissance the most fascinating of all the periods of history since the Periclean age of Athens.

The original centers and sources of the Renaissance culture—humanistic, artistic, philosophical, scientific—were the Italian city-states. These cities, and in particular the five mentioned above, had had a continuous existence from the days of republican and imperial Rome, and they had remained pagan to the core. The church had turned temples into cathedrals, and had even transmuted deities into saints, but it had never been able to eradicate the fundamental secularity of the Italian soul. Italy, too, was strewn with relics of classical antiquity. Its language, moreover, was so closely akin to Latin that the study of the Roman writers was an easy matter. The Latin revival begun by Petrarch in the first half of the fourteenth century prepared the way for the entry of Greek under Chrysoloras and his followers at the end of the century. Not only, however, did

continuity with classical times make the Italian city-states the natural leaders in the Renaissance movement; their political independence, their economic wealth, their social organization, all helped to confirm their primacy. The ruin of the mediaeval empire in the thirteenth century, followed by the captivity of the papacy at Avignon in the fourteenth, left them with unequaled opportunities of self-government and civic development in the fifteenth. The growth of their industries in the hands of the municipal guilds; the spread of their commerce under the protection of the state; the increase of their navies and the vast improvements in the art and craft of seamanship which they effected; above all, the evolution of banking and the weaving of the network of international finance—all these things gave their rulers and their leading citizens the power, as well as the will, to patronize artists and sculptors, to build churches and palaces, to found academies, to establish printing presses, to maintain scholars and men of letters.

From Italy the Renaissance spread across the Alps to continental Europe, reaching Germany first. In Germany the signs of the reawakening life and the inquiring mind were rather different from those displayed in Italy. The Christian religion had a stronger hold on the Germans than on the Italians; the solemnity rather than the hilarity of things impressed them. Hence their Renaissance scholars were men like Reuchlin and Melancthon who poured the light of the new learning upon the sacred Scriptures; their representative artists were men like Albrecht Dürer who subdued all his draftsmanship to the inculcation of moral lessons. Nay, the most typical German figure of the time is that of Luther himself, who converted the Renaissance for Germany into the Reformation.

France was hardly affected by the ideas and influences of the new era until after Charles VIII's fateful expedition to Naples in 1494. Janus Lascaris, in fact, during his eight years' sojourn in Paris, may be regarded as its pioneer. Its supreme representative, however, was François Rabelais (1495-1553), and his immortal creations, *Gargantua* and *Pantagruel*, are sufficient to show that in France the Renaissance meant not, as in Italy, the cult of pagan beauty nor, as in Germany, the quest for primitive Christianity, but rather the zest of a life of ribaldry, freed from the bonds of mediaeval reverence and restraint.

England had shown signs of an early Renais-

sance of her own. The poems of Chaucer, for all their mediaeval setting, had been an indication of the dawn of the modern mind. In the opening years of the fifteenth century, too, the zeal of Humphrey of Gloucester in gathering manuscripts, patronizing scholars, embarking on hazardous speculations, had been a clear precursor of the Renaissance spirit. The Wars of the Roses, however, had thrown the country back into mediaeval anarchy and darkness; and when the Tudor rulers gave the country peace and order once again, the course of events revealed the fact that during the interval of obscurity the Renaissance in England had been changed from a movement akin to the Italian to a movement akin to the German. Not men like Humphrey of Gloucester or Tiptoft, Earl of Worcester, but sober reformers and grave scholars, such as Linacre, Colet and More, became its representative figures.

In the Spanish peninsula religion of the mediaeval type remained dominant, and it precluded the entry of either Renaissance or Reformation. Eight centuries (700-1500) of almost uninterrupted crusade had made the maintenance and diffusion of the faith the prime concern of the loftier Spanish minds. This enthusiasm for the Cross, however, although it expelled humanism and depressed art, led to some very remarkable achievements which rank among the greatest and most characteristic of the age. It led to the voyages of discovery. The Portuguese pioneer Prince Henry the Navigator, as during forty years (1420-60) he built his ships, collected his charts, organized his expeditions and sent his seamen forth, was inspired and supported by the hope that he might reach the Christian kingdom of Prester John, might turn the flank of the Turkish Empire and might recover the Holy Land. He did not succeed in his purpose; but he did open up the way which later enabled Diaz to reach the Cape of Good Hope (1486) and Vasco da Gama to open the ocean route to India and the Far East (1498). Similarly Columbus, when on August 3, 1492, he set forth from Palos on his first great westward voyage, did so *in nomine d. n. Jesu Christi*, and went in order that he might open up the Indies and Cathay not only to the commerce of Europe but also to the missionaries of Catholic Christendom; and when the New World was discovered and the strange realms of the Aztecs and the Incas were reduced, the extirpation of heathendom and the imposition of the yoke of the church became the

prime preoccupation of the Spanish conquerors.

The discovery of the New World, like the Copernican discovery of the universe, had a profound and even more direct influence upon the social sciences. On the one hand it enlarged the spheres of both politics and commerce, giving rise to wholly unprecedented problems of property and power. On the other hand it prompted anxious questions by revealing to the speculation of the Old World religions wholly alien from both Crescent and Cross; systems of government profoundly different from any contemplated by either Aristotle or Augustine; codes of ethics in some respects superior to those of Christendom and yet totally unconnected with any of the codes current in Europe; social organizations obviously of immemorial antiquity and of intricate elaboration, nevertheless strikingly different from any modes of organization ever known on either the eastern shores of the Atlantic or the western shores of the Pacific; economic institutions curious in their naïveté but fascinating in their patent purpose to secure rational justice. It is deplorable that the investigation of these ancient aboriginal civilizations of the newly discovered America fell into the hands of a people so ignorant, so incurious, so bigoted, as the Spanish companions of Cortez and Pizarro. The fragments of information they have transmitted to us make us long for more. They told enough, however, to their contemporaries to quicken their imaginations and to set them dreaming of Utopias, Oceanas, New Atlantises, wherein politics preferable to those of a decadent Christendom prevailed. Above all, they gave new vitality and enlarged content to the old stoic conception of a state of nature superior to that of civilization; of a law of nature higher than the enactments of men; of a natural religion, simple and universal, underlying the creeds of all the churches and cults; and of a natural man, free and unsophisticated, who in primitive innocence lived the ideal life in the earthly paradise. The "noble savage" was the denizen of lands unknown before the days of Columbus; and the *Etre Suprême* of the deists of the age of reason rose into existence among the palm clad coral islands first seen by Magellan.

III. The impact of new ideas, the spread of new inventions, the revelations of the new astronomy, the discoveries of the new geography, the opening up of the new commerce—all these strange perturbing novelties displayed

themselves in a Christendom that was already in process of rapid and revolutionary change. The feature which, above all others in the sphere of political institutions, marks the period of transition from mediaeval to modern times, is the disintegration of the *res publica Christiana* and the substitution of the system of national states; that is to say, the dissolution of an ideal unity based on religion—a single Christian community governed under God by two joint rulers, viz. the Holy Roman pope and the Holy Roman emperor—and the establishment in its place of a number of fragmentary states each under its national monarch who tended to claim unlimited authority over all persons and in all causes, whether temporal or spiritual. This tremendous change was immensely accelerated by the many movements, just surveyed, which made up the Renaissance. On the one side the free thought of the Renaissance challenged the validity of the whole system of mediaeval orthodoxy, sapping the very foundations of the papal authority. On the other side the exploitation of the New World, the appropriation of the new trade routes and the conquest of the new commerce, were tasks beyond the competence of any power less imposing and less well organized for war than whole nations, led by belligerent monarchs and supported by all the resources of the militant state.

In other words, the struggle for colonies and for commerce which the geographical discoveries of Columbus, Vasco da Gama and Magellan inaugurated conduced to the establishment of absolute monarchies, supported by the dogma of the divine right of kings, and so put a stop to several most interesting and important movements in the direction of democracy and representative government which the thirteenth and fourteenth centuries had manifested. In England the Parliament under Edward III, and still more under the three kings of the house of Lancaster, had steadily advanced toward control over the executive. In France the feudal nobles, the communes, the *parlements*, the provinces had all made strong claims for autonomy. In Germany and the Netherlands the revived study and general reception of the Roman law had generated the idea of self-governing corporations administering their own affairs by an inherent right not in any way derived from the state; and this fruitful idea of group sovereignty had been eagerly welcomed by all sorts of corporate bodies, civil and

ecclesiastical, municipal and industrial, philanthropic and educational, that had coveted independence of alien control. The political speculations of mediaeval thinkers like John of Salisbury, St. Thomas Aquinas and Aegidius Romanus had strongly tended toward the limitation of royal power and the establishment of constitutional government regulated by the church.

The late mediaeval classification of law into *jus divinum*, *jus naturale*, *jus gentium* and *jus civile* had assisted the cause of the opponents of absolutism by placing the mere enactments of the secular ruler in the lowest category of obligatory commands. Even the humanistic revival in its early stages had tended in the same democratic direction. For the *Politics* of Aristotle had made familiar the idea of a state in which the citizens had held complete authority; while the story of the Roman Republic, as told by Livy, was full of the records of fights for freedom and the expulsion of tyrants.

But, as Herbert Spencer has so conclusively demonstrated, the development of free institutions is dependent on the maintenance of peace and on the organization of society for industrial ends. The intense militancy of this transitional age, which saw the disruption of mediaeval Christendom and the struggle for overseas dominion, was such as to throw back for a couple of centuries the movement toward popular government, and in the meantime to make the autocracy of warlike monarchs inevitable. The men of the West, in their passion for power and their lust for wealth, ceased in the main to feel any concern for either sanctity in religion or freedom in politics. The principle of nationality became rampant. The old bonds which had held together the clergy of Christendom in a common church, the monks and friars in cosmopolitan orders, the knighthood of Europe in a fraternity of chivalry, the scholars of all universities in curricula always the same and a language everywhere Latin—all these mediaeval bonds were broken, and the people of the several countries of the continent (French, Spanish, Portuguese and so on) regrouped themselves as nations for purposes of commerce, colonization and war. The old "estates of the realm" forgot their former quarrels as they combined for aggression or defense. Vernacular languages supplanted the Latin which had for long been the universal vehicle of culture, and the French which had made itself the tongue of chivalry. Even the church, which stood, above

all things, for the fatherhood of God and the brotherhood of man, tended to split itself up into national sections that, even where they did not become definitely heretical, became decidedly schismatic. Catholicism in Spain and Gallicanism in France were at times hardly less resistant to Roman authority than Lutheranism in Germany and Anglicanism in Britain.

Nationality is fundamentally a psychological phenomenon. England was the country in which it first realized itself. Edward I's determination to unite the island of Great Britain by subjugating Wales and Scotland made an irresistible appeal to the patriotic passions of all classes of his subjects, welding them together for aggressive war. Still more did the struggle with the French that broke out in Edward III's day—the Hundred Years' War—caused, as it was, not so much by dynastic claims as by the clash of rival maritime and commercial interests, join all the orders of the people together to maintain English prestige and vindicate national honor. Such discordant factors as remained in England at the close of the Hundred Years' War—e.g. feudal nobles and ultramontane clergy—were so weakened by the subsequent Wars of the Roses that it was easy for the Tudor monarchs to eliminate them and to lead the whole "commonwealth of this realm of England" on patriotic adventure. The establishment of the Tudors at the end of the fifteenth century, indeed, may well be taken as the event that marks the unification of the English nation. The formation of the French nation, although different in process, was achieved also about the same date. Under Louis XI the centralization of the administration was completed; the feudal nobility reduced to impotence; the royal autocracy assured. Under his son Charles VIII Brittany, the last of the great independent fiefs, was (through the marriage of its duchess to the king) subjected to the authority of the crown. In that same closing decade of the fifteenth century, too, Spain brought to a termination its eight century crusade, when the united forces of Castile and Aragon (long sundered by fratricidal conflicts) joined to reduce Granada, the last stronghold of the Moors in the peninsula.

The almost simultaneous attainment of nationhood by England, France and Spain—to say nothing of Scotland, Scandinavia and the Netherlands—involved a portentous change in the politics of Europe. The achievement of solidarity at home marked the beginning of adventure abroad. Consciousness of power led

to aggressive enterprise. Not only were the high seas and the newly discovered regions of the Americas and the Indies made the scenes of furious conflict between English, Spaniard, French and Dutch, but the regions of old Europe which had not succeeded in attaining unity and order were converted into battle-grounds for contending depredators. In particular, two great countries whose inhabitants, although growingly conscious of nationhood, were unable to secure any sort of effective unification, became the "cockpits of Europe," the fields where alien invaders waged their wars, gathered their plunder and worked their will. These two were Germany and Italy. Concerning the causes that delayed the unification of Germany and of Italy until the nineteenth century this is not the place to speak at length. It is enough to note that the intimate association of Germany with the Holy Roman Empire and of Italy with the papacy held them fast bound to the mediaeval system.

Italy was the first to suffer from her failure to weld her diverse small states into a national monarchy of the new type. At the moment when France, Spain and England were completing their consolidation under strong kings, that is, at the end of the fifteenth century, Italy was divided among five greater powers, viz. Naples and the papal states in the south, Venice and Milan in the north, with Florence holding the balance in between. Commonly Venice and the papacy were allied against Milan and Naples, but commutations and permutations among the microscopic five were so frequent and so bewildering that the study of Italian history during the period of the Renaissance is like the threading of an intricate maze. Moreover never was diplomacy so utterly devoid of scruple as it was at this time in the Italian peninsula; never was war waged with so diabolical an admixture of treachery and cruelty; never were poison and the dagger so freely employed to supplement the lies of the politicians and to redress the failures of the mercenary soldier.

No doubt the Italian intellect was quickened and sharpened by the urgent need for incessant alertness in the midst of this unmitigated struggle for existence. The period of wildest and most confused conflict was precisely the period of the climax of the Renaissance—the period wherein flourished Leonardo da Vinci, Michelangelo, Raphael and their compeers of equally immortal memory. But to the commonalty of

the peninsula it was little satisfaction to know that treasures of art were being accumulated and masterpieces of literature written, when at the same time their fields and vineyards were being trampled down by lawless companies and their homes broken up by unpunishable tyrants. And if the condition of things was almost intolerable when the disturbers of the peace were still limited to persons and powers proper to the peninsula, how much more than intolerable did it become when into the seething cauldron of Italian politics French, Spaniards, Swiss and Germans began to dip their agitating spoons. The expedition of the French king, Charles VIII, to make good his claim to the throne of Naples in 1494, marks the commencement of the serious intervention of foreign powers in Italian affairs. To expel the French from Naples Ferdinand of Aragon, the inheritor of another shadowy right to the Neapolitan crown, sent his invincible Spanish infantry. Then, in the north, Valois and Hapsburg became involved in furious conflict for the duchy of Milan, and alien mercenaries, Swiss on the one hand and German on the other, were brought over the Alpine passes to aid in determining the doubtful issue. So was Italy ravaged from end to end by *condottieri* devoid of honor, and by auxiliaries lustful and merciless. To a patriotic Italian at the beginning of the sixteenth century the political prospect was one of almost unrelieved gloom.

IV. It was at this critical moment in Italian history that Niccolò Machiavelli (1469-1527) began to play his memorable part upon the Florentine stage—a part how strikingly different from that played by Dante (1269-1321) on the same stage just two centuries earlier! Nothing, indeed, can more effectively bring home to the student the completeness of the transformation that marked the transition from mediaeval to modern times than a comparison of the *De Monarchia* of Dante with *The Prince* of Machiavelli. All Dante's great ideas of divine governance, universal empire, perpetual peace, eternal justice and the general reign of law have vanished away, and in place of them has come a *Realpolitik* wholly free from all idealistic elements—a political system concerned solely with current facts, entirely regardless of both the precepts of religion and the dictates of morality, completely engrossed with the art of government to the entire exclusion of all speculation respecting the theory of the state.

deliberation is wholly touching the safety of the fatherland there ought to be no consideration of just or unjust, pitiful or cruel, honorable or dishonorable, but rather, all other respect being laid aside, that course ought to be taken which may preserve the life and maintain the liberty thereof." From *The Prince* (ch. xxviii) comes the echo: "Let a prince, therefore, take the surest course he can to maintain his life and state: the means shall always be thought honorable"—and the means to which Machiavelli alludes are the merciless ferocity of the lion and the unscrupulous craftiness of the fox. If we ask why Machiavelli troubled to put his ideas down twice—once at leisurely length in an endless string of comments upon the history of the Roman Republic, and once in a brief but pungent letter of advice to an individual ruler, the answer is that the purposes of the two works were wholly different. *The Discourses* were intended for the generality, and they were as a matter of fact read to a numerous company from time to time in the gardens of Florence; they were intended to prepare the public mind for the setting up of the Italian kingdom, modeled on the Roman Republic, and to inoculate the squeamish against any shock which their consciences might receive from the means employed in its establishment. *The Prince*, on the other hand, was a private and confidential document giving precise instructions of a most secret and intimate nature to the individual superman through whose agency the deliverance and unification of Italy were to be effected. Who was this superman—this hero amid a multitude of poltroons—on whom Machiavelli fixed his hopes? In his early days the great *condottiero* Castruccio Castracani had been the center of his expectation; later, when he was secretary, the brilliant but wholly non-moral Cesare Borgia had appeared likely to be the predestined man; Cesare's death in 1507 had left no one but Giuliano de' Medici to whom the patriotic nationalist could look. Can Machiavelli ever seriously have believed that Giuliano had either the spirit or the ability to carry through the tremendous and terrible program assigned to him—the formation of a native army, the expulsion of the foreigner, the debasement of the papacy, the unification of the peninsula, the establishment of a national state? Probably not. Most likely all that Machiavelli immediately hoped for was his own restoration to office and influence in Florence. Not even this, however, resulted. Giuliano de' Medici died in

1516, and Machiavelli transferred his solicitations to his brother and successor Lorenzo. But to him likewise he appealed in vain. Lorenzo neither recalled him to Florence nor took any steps to realize his political ideal.

Machiavelli's *Prince* had no apparent influence whatsoever during Machiavelli's own lifetime. Five years after his death, however, in 1532, Pope Clement VII, nephew of the two Medici to whom the book had been presented, let it loose upon the world. It is eloquent of the corruption of Renaissance Italy that the Machiavellian politic should not have shocked in any way the papal conscience, and that the publication under papal auspices of a work in which reasons of state take precedence of all the dictates of morality and religion should have caused no surprise in the peninsula. Once published, it spread rapidly. Translated into all the languages of Europe, it became the textbook of tyrants and conspirators. It is difficult to estimate how far it was to be held responsible for such dark deeds as the massacre of St. Bartholomew's Day, 1572. Not less difficult is it to say to what extent the conduct of such typical Machiavellians as Frederick the Great, Napoleon I and III, Bismarck and Cavour was determined by a study of its precepts; possibly the accordance of their conduct with its precepts was a mere coincidence. For the dissociation of politics from ethics has not been a phenomenon peculiar to any one age or any single locality. What makes Machiavelli unique is his open and unashamed avowal of principles which men usually (like Cavour) conceal or (like Frederick) ostentatiously repudiate. His works, with their frank and naïve wickedness, mark as with a flash of sudden revelation the end of the amiable theorizing of the estimable mediaeval ecclesiastics concerning the relations of the two powers, the two lights, the two swords, the two small fishes and the rest of the miscellaneous collection of visionary dualities; and the reunion of the theory and practise of politics in a world of new and militant states.

V. Machiavelli's *Discourses* and *Prince* are not the only works of his enforced and unwelcome leisure that merit notice as evidences of the change passing over the social sciences during the period of the Renaissance. His *Art of War*, remarkable as the first scientific treatise on military tactics, indicates clearly the abandonment of the mediaeval belief that the destinies of nations are in divine hands and are

determined according to the decrees of everlasting justice, and the assumption of the view that they are in the keeping of the nations themselves and are determined by the standards of mere craft and force. In this book, with a curious mixture of wisdom in generalities and folly in particulars, Machiavelli exalts pagan virtue as against Christian humility; a national militia as against hired mercenaries; infantry as against cavalry; and pikes and swords as against those deceptive novelties, firearms! Still more significant sociologically is his *History of Florence*. Utterly unlike both the earlier chronicles, such as that of Villani, and the collections of learned lumber to which such antiquarians as Aretino gave the name of histories, it is concerned wholly with the politics of Machiavelli's own day. Written in Italian and not in Latin, expressed in vivid and unconventional phraseology, it deals mainly with the events of that very recent period 1434-92; and where it treats of the earlier period it does so merely in order to discover the causes of current movements or to illustrate them by analogies and parallels. It piles up examples, for instance, to show how treacherous and untrustworthy mercenary soldiers always have been, and how all decisive victories have been won by native levies. Similarly, greatly daring, it indicates again and again how appalling a disaster has been the assumption of temporal power by the papacy, and how the first step toward the unification of Italy must be the termination of this ecclesiastical usurpation.

The treatment of history as a handmaid to politics, so strikingly illustrated by Machiavelli's *History of Florence*, was characteristic of many other historical writings of the period of the Renaissance and Reformation. History, and particularly ancient history, was seen, on the one hand, to provide a storehouse of precedents and examples infinitely valuable as guides to the conduct of practical affairs. History, and particularly modern history, was recognized, on the other hand, as the indispensable informer respecting the antecedents of the problems of the current day. Hence writers such as Blondus and Guicciardini, on the one side, or Camden and Grotius, on the other, compiled their histories or their annals not in order to provide amusement for the passing hour, nor yet in order to point moral lessons, but in order to supply statesmen with materials for the formation of judgments, and to furnish patriots with weapons for the defense of their country.

The historical works of the Renaissance and Reformation period, since they were of the nature of politicians' handbooks, although they were characterized (in sharp contrast with mediaeval chronicles) by coherence and unity of design, were of course highly partisan in nature and controversial in tone. They aimed at stating a preassumed case or at defending a prejudged cause. They were uncritical in their use of materials, unscientific in their treatment of evidence and wholly unscrupulous in their arguments and conclusions. The patriotic histories, such as those of Machiavelli and Guicciardini, pointed the way; but the theological histories became the great examples of the new mode.

That history should have been one of the main weapons with which the battles of the Reformation were fought is by no means remarkable. For the keynote of the Reformation was "Back to Primitive Christianity," and consequently the issue turned on the historical questions, first, what was primitive Christianity, and, secondly, by what process, whether of development or of corruption, did mediaeval Christianity come to diverge so widely from the primitive model. Hence rival bodies of theologians, such as the Magdeburg Centurionists, on the Protestant side, and the Benedictines of St. Maur, on the Catholic side, gave themselves to the enormous labor of rummaging the lumber rooms of antiquity in order to provide their partisans with offensive missiles or with material for defensive barricades.

But the Reformation was more than a matter of academic controversy between divergent schools of ecclesiastical historians or antagonistic companies of theologians. It was a movement that gathered to itself and incorporated many revolutionary tendencies in the worlds of society and politics for which the time was ripe. Besides being a return to the simplicity of the Gospel and a reaffirmation of the doctrine of justification by faith, it was also a revolt of the laity against clerical tutelage; a rebellion of the individual against authority; a rising of emancipated human reason against tradition and convention; a protest of the national conscience of man against the corruption of the Roman penitential system; an attack of the secular power upon the accumulated wealth of the religious. Further, as it spread from Germany throughout Europe and as the comparatively mild dissidence of Lutheranism was supplemented by the thoroughgoing anti-Catholicism of the Cal-

vinistic organization, the Reformation became involved in one country after another with social and political movements with which it had no natural or necessary affinity. Generally it appealed more to the Teutonic than to the Latin mind; so that it might seem to have been the belated revolt of the barbarian against his Roman master. In many lands it became associated with the cause of national independence, and the association was so complicated that it is difficult to say whether politically the Reformation is to be regarded as the product of the national state, or the national state the product of the Reformation. At any rate nationalism and reform were frequently inextricably interwoven. For example, much of the support which John Knox received in Scotland came from powerful patriots who were determined to cut the fetters that were dragging down their country into subjection to France; similarly Calvinism made headway in Holland as part of the national resistance to the tyranny of Catholic Spain; so, too, did Sweden adopt Lutheranism precisely at the moment when she was shaking herself free of Danish control. Internal politics, moreover, did much to determine the attitude of governments and of large classes of their subjects toward the Reformation movement. In England, for instance, the king took the lead in the revolt against Rome; and he used the religious power of the reformers as a means wherewith to beat down the remnants of the mediaeval nobility, to subjugate and despoil the over-wealthy clergy, and to establish the royal autocracy. In France, on the other hand, the Valois monarchy, whose conflicts with the Hapsburgs in Italy made papal friendship a necessity, set its face against both Luther and Calvin. Hence, by way of reaction, all opponents of kingly power and centralized administration—and in particular the feudal nobility and the semi-sovereign communes—tended to join the company of the Huguenots. And the Huguenots, in the fury of their resistance to the royal authority, did not hesitate to ally themselves to the enemies of France and to mortgage French territories to their country's foes. Hence in France nationalism identified itself with the Counter Reformation, and the cause of Calvinism became not (as in Scotland or Holland) the cause of patriotism but the cause of disloyalty, rebellion and treachery. So, too, in respect of Spain: the mere fact that the Dutch rebels were Calvinists and the English pirates Protestants was enough to make the grandees of

Castile and Aragon fanatical in their zeal to maintain the ascendancy of Rome. Catholicism and empire became synonymous terms.

VI. Since the Reformation had such different political and social affinities in different parts of Europe, and since, moreover, it was marked by a general revolt against authority and by the proclamation of a novel independence of judgment, it is not surprising that in the sphere of sociology it should have given rise to many and diverse varieties of speculation and theory. At one end of the scale the old problem of the relations of church and state assumed new forms and met with strange solutions, discussion finally centering round the question of the limits of religious toleration. One thing, at any rate, was made clear in the course of the controversy, and that was that the ideal *res publica Christiana* of the Middle Ages had been irremediably shattered and that the two societies, secular and sacred, stood forth as separate and naturally antagonistic entities. At the other end of the scale the long quiescent question of the relations of the individual to society began to be raised in many acute forms. Not only did heretics and antinomians claim entire freedom of faith and complete emancipation from external restraints; but radicals and communists in infinite variety of fantasy challenged the whole social and economic order, and formulated grandiose schemes for the reorganization of heaven and earth.

Martin Luther, the pioneer reformer, more of a moralist than a theologian and more of a German than either, was the first who had to face the problems created by the disruption of Christendom. The position of antagonism to both papacy and empire which, with prodigious courage, he assumed in 1521, was one of a peril so extreme that only a few years earlier no one occupying it could have hoped to escape fiery destruction. His only chance of safety and survival resided in the possibility of the support of the German nation as against the dominance of the Roman curia, and the support of the princes of the empire as against the alien Charles v who, although a foreigner, half Fleming and half Spaniard, had just been elevated to the imperial throne. His politics therefore were, on the one hand, intensely nationalistic and, on the other hand, intensely monarchic. He made his appeal in the German language to the Christian nobility of the German nation; its insistent note was emancipation from

the Latin yoke. He exalted the power of the prince, deriving it from God, and asserted, in language borrowed from St. Paul, the duty of all subjects to obey. He glorified the state as the supreme authority in all causes whether secular or sacred, thus preparing the Teutonic mind for the reception, three centuries later, of the *étatiste* doctrines of Hegel and Treitschke. Nevertheless he had to make some concession to relativity in his absolutism. He could not forget that the monarch whose divine prerogative he exalted might be a persecuting Catholic, like Charles v in Spain. He therefore had to impose limits both on the authority of the ruler and on the submission of the subject. He found much difficulty in framing an exception to the general rule of passive obedience which should not itself become a general rule of active disobedience. Finally, with much hesitation and vagueness, he admitted that if a monarch violates the divine law he forfeits the claim to command the submission of his subjects. This reluctant but inevitable admission was enough for the antinomian rebels of the day, to each one of whom the divine law was a matter of direct personal revelation. In revolts that set all the restraints of religion and morality at defiance they reduced large tracts of Germany to chaos. Hence, in order to save his nation from ruin and his religious organization from hopeless discredit, Luther had to insist that the authority of a pious Protestant prince was unlimited, and to call upon all the pious Protestant princes of his communion to suppress the peasants' risings.

Philip Melanchthon, Luther's great disciple and colleague, pondered politics from a loftier and less opportunist point of view than his leader. He was a man of profounder scholarship than Luther, and of more philosophic mind; moreover he was less perturbed by the urgent need to solve the practical problems of the hour. Not without justice has he been called the Protestant Aquinas. Drawing upon an extensive knowledge of the scholastic philosophy, the canon and civil laws, the politics of Aristotle and the ethics of the New Testament, he made a serious attempt to frame a coherent system of social doctrine applicable to the new ecclesiastical condition of things. The basis of his system is the sovereignty of law, primarily, of course, the divine law, the directly revealed will of God; but, secondarily, the law of nature, the unrevealed law of God, written upon the conscience of every man born into the world. By reference to this supreme and authoritative

double code of law Melanchthon defends the institution of government and maintains the right of princes to rule. He contends that the principal purpose of secular administration is the establishment of peace and the provision of conditions in which true religion may flourish. He insists that so long as the state is duly performing its divinely appointed functions, all its subjects are bound to obey its commands. He refrains from discussing what ought to happen if the state should exceed or fall short of its duty, and if it should violate the precepts of the divine legislator. But by implication he says the same as Luther, viz. that in the last resort Christians must obey God rather than man, and consequently that the right and duty of resistance exist. No reformer could possibly avoid sanctioning rebellion in some degree or other. In the endeavor to do so most of them suffered agonies.

Ulrich Zwingli was a much less conspicuous reformer than either Luther or Melanchthon. His stormy career, which centred in Zurich, was cut short by death in battle (1531) when he was but forty-seven years old. In so far as the eight volumes of his works contain any meanderings from the straight paths of theology into the mazes of politics, they show that in an interesting and significant way he reverted to the mediaeval ideal of the *res publica Christiana*, that is to say, to the ideal of a single society—church on its spiritual side, state on its temporal side—in which the whole community is joined together. But it was a reversion with a difference. It was no longer a Holy Roman Empire comprising an undivided Christendom in its scope but merely the city and canton of Zurich wherein Zwingli himself exercised the combined ecclesiastical and secular authority. Within the limits of this small reformed Christian community he claimed absolute and universal authority, and he insisted on the duty of passive obedience from his subjects.

For a short time Zwinglianism planted itself in the city of Geneva. The Zwinglian principle of religious autonomy and political independence commended itself to the citizens of that aspiring commune in their struggle to retain their freedom as against the dukes of Savoy and other formidable foes. Soon, however, Zwinglianism was supplanted by another type of reformed religion still more potent as an organ of militant independence. In 1536 John Calvin, fleeing from persecution in France, made his way to the fair city on Lake Lemane; in 1541,

after striking vicissitudes of fortune, he established an ascendancy there that endured until his death in 1564. The political principles of Calvinism, as set forth with admirable precision in the closing sections of *The Institutes*, are theocratic and republican. Their foundation is the universal sovereignty of the divine will. The superiority of the spiritual authority over the temporal authority is asserted with as much emphasis as ever it had been asserted by Pope Boniface VIII in his famous bull, *Unam sanctam*. Nevertheless the secular government is necessary as the agent of the ecclesiastical, and within its own proper sphere it is equally of divine institution. Its function is to enforce the decision of the elders of the church, to maintain the cause of the reformed religion, to secure external and internal tranquillity. Its form, like that of the presbytery, should be republican: it should consist of the aristocracy of saints. The duty of the rank and file of the elect is passive obedience. But even Calvin, although with obvious unwillingness, is compelled at the very end of his discourse to admit the fatal exception. What if the secular authority, forgetting its duty to its spiritual superior, prove naughty and recalcitrant? In two cases Calvin allows that it may be, and indeed must be, resisted. First, if it be "tyrannical" it may be opposed in due constitutional form by the ephors; secondly, if it be "wicked" it must be met by the general resistance of the whole community. Since the question as to what constitutes "wickedness" is left to the judgment of the individual believer, it is clear that a breach is made in the dyke of authority sufficiently large to admit all the flood of rebellion. For the faithful Calvinist, whenever he found himself in either a Catholic or a Protestant state, tended to identify "wickedness" with refusal on the part of the government to accept the full presbyterian system. Hence Calvinism, for all Calvin's precautions, became the creed of rebels.

VII. For some quarter of a century (1520-45) the Reformation in its various manifestations—Lutheran, Zwinglian, Calvinistic, Anglican—carried all before it. The Catholic church, because of its failure to correct the abuses which had corrupted it in the later Middle Ages, had lost its hold on the conscience of Christendom. Toward the close of Luther's life (1546) it seemed probable that not only in Teutonic countries, but even in France, Spain and Italy itself, Catholicism would be swept away alto-

gether. In these desperate circumstances, however, the menaced church recovered itself, carried through the long needed reforms and under a series of new popes, very different from the depraved worldlings who had held the papal chair during the Renaissance, stemmed the tide of disaster. New religious orders, in particular that of the Jesuits (1534), organized themselves to combat the new heresies; the Index was instituted to regulate the reading of the faithful; the Inquisition was directed to the extirpation of the unfaithful; the doctrines of the church were formulated with a new precision, as against the new sectaries, by the Council of Trent (1563).

The Catholic recovery began; and before the close of the sixteenth century one-half of Christendom was securely regained. Not without strenuous resistance, however, did the reformers surrender their conquests, and for nearly ninety years (1559-1648) Europe was torn by religious wars marked by a sanguinary ferocity unknown in earlier conflicts. The persecutions of Alva in the Netherlands (1567-73); the massacre of St. Bartholomew's Day in France (1572); above all, the long protracted atrocities of the Thirty Years' War in Germany (1618-48) necessitated not only the establishment of a state sovereignty strong enough to curb the fury of the religious fanatics but also the reconsideration of political theory, the formulation of a principle of toleration and the institution of international law. We can do no more than glance at some of the lines taken by the thought of this disturbed but energetic age.

The first doctrine to be developed was that of the right of resistance to tyrants—a tyrant being any ruler who did not support the resister's form of religion. It was a doctrine urgently needed both by Protestant subjects of such monarchs as Philip II of Spain, Mary of England or Charles IX of France, and by Catholic subjects of such monarchs as Henry VIII of England, Henry III of France or William of Orange. It was developed by a number of thinkers on both the Protestant and the Catholic sides. Of the Calvinistic statements of the case by far the most effective is that of the *Vindiciae contra tyrannos* (1579), formerly attributed to Hubert Languet but now generally assigned to Philippe Duplessis-Mornay. It boldly advances, on the basis of Old Testament history, Roman law and feudal principle, the contractual theory of the source of political obligation; contends that sovereignty originates in and continues to

reside in the people; and argues that kings, who are mere executive agents, can properly be removed if, whether by tyranny or by wickedness, they break their engagements.

On the Catholic side the principal formulators of the theory of the right of rebellion were the Jesuits. To the horror of a good many Catholics of the old school they frankly abandoned the politics of St. Thomas Aquinas and treated the state as a purely human (if not diabolic) institution, having no claim whatsoever either to challenge or to share the divine authority of the church. The greatest and most lucid of the Jesuit publicists, Juan de Mariana, in developing this idea in his *De rege et regis institutione* (1599) formulated a political philosophy strikingly similar to that which half a century later Thomas Hobbes elaborated in his *Leviathan*—using it, however, for the exaltation of the ecclesiastical and not of the secular power. He pictures a state of nature, subsequent to the fall of man, thoroughly evil, in which everyone's hand is against that of his neighbor; he describes the emergence of society from this condition of primitive chaos by means of a contract; he supposes a ruler to be chosen by the newly constituted people, and he depicts him as placed in an authority which is strictly limited by the terms of his appointment. If he breaks his engagement, whether through tyranny (that is, violation of the constitution) or through wickedness (that is, departure from the true faith) he can properly be removed, either openly by formal deposition or, if this fails, by assassination.

It was the sanction of assassination by the grave fathers of the church, both Catholic and Calvinistic, that constituted one of the worst horrors of this dreadful period of the wars of religion. Rulers in every country where the conflict between the new faith and the old was waged were subjected to the paralyzing peril of sudden death at the hands of pious fanatics who were assured by their spiritual chiefs that they were doing God service in removing tyrants. William of Orange in Holland had survived five attempts upon his life before he succumbed to the pistol of Balthasar Gerard in 1584; Elizabeth of England informed a French ambassador that, thanks to Burleigh's vigilance, no fewer than fifteen plots to compass her death had been frustrated; Henry IV of France escaped nineteen would-be assassins before he fell beneath the knife of the twentieth, the devout Ravaillac, in 1610.

The dominance of the doctrine of rebellion and tyrannicide in the political theory of the late sixteenth century, coupled with the universality of civil wars and the persistence of assassination plots, caused both practical statesmen and patriotic thinkers to ponder means whereby fanaticism could be restrained and order restored. The men of affairs had to seek modes of religious compromise and methods for restoring strong monarchical governments. The theorists had to try to discover some workable principle of toleration and some valid arguments for monarchical authority. We are not now concerned with the history of the process whereby—e.g. in France by the Edict of Nantes (1598) and the strong rule of Richelieu, (1624-42)—religious strife was quelled throughout Europe and order reestablished. Our attention must be concentrated on the speculative writings whereby the return to sanity and security was fostered.

Foremost among the champions of good government and the advocates of religious toleration was Jean Bodin (1530-96), one of the ablest Frenchmen of his day, a faithful servant in turn of the renegade Catholic Henry III and the renegade Huguenot Henry IV. In an age of religious fanaticism he was eminent for indifference and ambiguity. What his own opinions were it is impossible even now to determine. Mercier assures us that he was a Catholic; De Thou claims him as a Huguenot, and it is certain that as such he was marked down for extermination in August, 1572, escaping the fate of Coligny only by the lucky chance that a window was open and that he himself was agile and daring. Patin says that he was a Jew and so lends support to a tradition, recorded by Monsieur Chapellain, that on his mother's side he was descended from a family of Spanish Israelites driven from the peninsula by the persecution of 1496. Bayle characterized his religion as "amphibious," while Gillot, who had known him, denied (in a letter to Scaliger, 1607) that he had any religion at all, concluding with the words: "Il mourut comme un chien, *sine ullo sensu pietatis*, n'étant ni juif, ni chrétien, ni turc." These are high encomiums for the period to which they relate: a few more of such amphibians would have been all the better for the peace of the world. Even as things were, his influence was great and beneficial. For he was the guide and counselor of the party of the *politiques* who in France secured some sort of toleration by the issue of

the Edict of Nantes (1598), and some sort of order by the establishment of the Bourbon monarchy. His two most notable works from our point of view are, first, his *Heptaplomeres* (circulated in manuscript and never yet fully printed) and, secondly, his *Republic* (published in French in 1576 and in a revised Latin version in 1586). The *Heptaplomeres*—whose curious title no one has been able to explain—is in form a discussion, free and passionless, between seven men representative respectively of the tenets of Catholicism, Lutheranism, Zwinglianism, Judaism, Mohammedanism, atheism and neo-Platonic mysticism. The outcome of the protracted but amiable debate—of which the honors are shared between the Jew and the neo-Platonist—is that absolute truth is unattainable and that the only practicable policy is therefore that each should hold his own view and tolerate that of his neighbor. The book ends with the noble words attributed by Cassiodorus to Theodoric the Ostrogoth: “Religionem imperare non possumus, quia nemo cogitur ut credat invitu.”

This same principle of lofty tolerance is quoted again by Bodin in his *Republic* (bk. iv, ch. vii), but the object of that great work is far larger and more comprehensive than the mere advocacy of a liberal religious policy. The *Republic* is an immense treatise, comprising in its twelve hundred and twenty-one octavo pages well over a quarter of a million words. It is the most complete and systematic treatment of the whole field of political and social speculation written since the days of Aristotle. Of its six books the first treats of the family and the state. The family is the basis of the state, and groups of associated families form the material out of which it is constituted. And yet it is not constituted by consent out of the voluntary co-operation of these groups but by force because of their conflicts with each other. Force is the essence of that sovereignty which is the distinctive mark of the state: “Majestas est summa in cives ac subditos legibusque soluta potestas.” Book II is less controversial; it distinguishes, in a way which later political theorists (e.g. Hobbes) would have done well to remember, between state and government, describes the three possible forms of state (monarchic, aristocratic, democratic) and indicates the innumerable varieties of forms of government. Book III is dull and technical: it discusses at dreary length the different types of legislative assemblies, executive magistratures and judicial

courts; treats of the various *sodalitia* (colleges, communes, corporations) within the state, and contends that all are subordinate to the sovereign political authority; expounds the rights and duties of citizenship. Book IV follows closely the lead of Aristotle in considering the causes of revolution and in seeking to discover the secret of the fall of states. It goes beyond Aristotle, however, in arguing that by means of astrology the fate of kingdoms and empires can be foreseen. If Book IV follows Aristotle, Book V in a most interesting way anticipates Montesquieu. It is a pioneer study of the influence of geographical conditions in general, and climate in particular, upon political and social institutions. It distinguishes three primary climatic regions—the frigid north, the torrid south and the temperate middle region—and it discusses with a wealth of learned illustration the features peculiar to each and the institutions appropriate thereto. Nothing could have been a clearer indication of the doctrine of political and even religious relativity. No form of state or government, no sort of ecclesiastical organization, has any absolute validity. All is dependent on time and circumstance. After this remarkable utterance Book VI comes as an anticlimax. Apart from a rather novel treatment of public finance, it is merely an omnium-gatherum comprising miscellaneous odds and ends too important to be left out altogether but not sufficiently relevant to the main themes of the book to have been included hitherto.

VIII. Bodin's *Republic* was a seminal work full of original and striking ideas. Its main tendency was the exaltation of the state over the church, the assertion of the almost unrestricted sovereignty of the secular ruler and the advocacy of the principle of religious toleration in the interests of peace. Bodin's doctrines, of course, did not please everyone. Both zealous Calvinists and devout Catholics objected to his secularity and to his debasement of the spiritual power. His conception of religious toleration appeared to most of the persecutors and would-be persecutors of the day as a weak and wicked surrender to the devil. Even those who agreed with his doctrine of state sovereignty, his advocacy of the subjection of corporations to the central power, his commendation of monarchy and his condemnation of regicide, were often dissatisfied with the way in which he treated the state as having no other sanction than force, and the king as

possessing no higher sacredness than utility. They felt that a religious basis was needed for the state if it were to maintain itself against the sectaries, and that only if kings were hedged in by divinity could they hope to escape the diabolical weapons of the assassins.

Prominent among these theological defenders of monarchy was William Barclay (1546-1608), a Scottish Catholic who, having gone to France as a youth to study law, remained there as a professor and public servant. In his most notable work, *De regno et regali potestate* (1600), he argued (against Bodin) that royal authority was not derived from conquest or based on force, and (against the Calvinists and Jesuits) that it was not a mere matter of contract. On the contrary, he maintained that kings were the representatives of God and that they derived their authority from heaven. On this ground he taught the duties of passive obedience and active support on the part of subjects, and condemned the prevailing practice of regicide as being as obnoxious to the King of Heaven as it was inconvenient to the kings of earth.

The doctrine of divine right thus enunciated was not a novelty among men. It had many antecedents in the sacred books of the East. It was clearly foreshadowed both in the practise of the Old Testament and in the precepts of the New. It had been developed by the supporters of the mediaeval emperors in their controversies with the supporters of the mediaeval popes. The emperor, they contended, derived his dignity direct from the Deity and not mediately through the papacy. It had been adopted and adapted by such national kings as Philip IV of France and Edward III of England when circumstances brought them into conflict with the ecclesiastical power. It derived a new importance after the Reformation when bulls of excommunication and deposition began to be directed from the papal curia against heretical and schismatic rulers. Still further was its value enhanced when Jesuits like Mariana and Calvinists like George Buchanan, commenced to formulate the contract theory of the relation between monarchs and their subjects, with the appendant dogmas of the contingent rights of rebellion and tyrannicide.

At the end of the sixteenth century two kings of the front rank were ruling in spite of the strenuous antagonism of the papacy—Henry IV in France and James I in England and Scotland. They and their defenders asserted, as against the papal claims to absolve their sub-

jects from the bonds of allegiance, not only the divine right of kings but further their divine hereditary right. They emphasized the patriarchal principle of primogeniture as the sole mode by means of which the sacred authority to govern was transmitted. Henry IV was content to let William Barclay speak and write on his behalf; but James I, proud of his pedantic learning, himself took pen in hand and, in order to exalt his royal prerogative, produced a series of works, of which the *True Law of Free Monarchies* (1598) is the most considerable. He found the dogma of the divine hereditary right of monarchy a potent instrument of defense against very varied foes. It protected him against popes who claimed power to depose him; against parliaments which professed to restrict him; against presbyteries which pretended to regard him as their agent and "God's silly vassal"; against Puritans who proposed to assassinate him. Later statements of the divine right doctrine were made in England by Sir Robert Filmer and in France by the courtly Bossuet.

IX. The problems dealt with by Bodin and by Barclay, by Mariana and by James I, were problems of internal government. The principles of their solution were sought in scripture, in history, in Greek philosophy and in Roman law. Besides these domestic problems, however, the new age brought up for consideration problems of a wholly novel character in the realm of international and interracial relations. The discovery of America; the establishment of colonial empires by Spaniards, Portuguese, Dutch and English; the founding of factories in India; the development of intercontinental commerce; the subjugation of non-Christian peoples—all these phenomena of the new world of sovereign national states gave rise to urgent questions in the sphere of ethics, economics, politics and law.

It was useless to appeal to the old authorities for the settlement of these new problems. For, on the one hand, their utterances were irrelevant and, on the other hand, they were not recognized as authoritative. On issues that divided Protestants from Catholics it was vain to cite the decisions of popes and councils; on issues that concerned both Christians and non-Christians it was no good to appeal either to the Scriptures or the early fathers. What was needed was some recognized norm of conduct that would be recognized as binding on man,

merely as man, all the world over and in every age. This norm was supplied by the great Dutch thinker Hugo Grotius (1583–1645) in the law of nature with its supplementary law of nations.

The conception of the *lex naturalis*, or *jus naturale*, was as old as the stoic philosophy. It was recognized by St. Paul (*Romans* II. 14); it was developed by the mediaeval schoolmen; it was incorporated by St. Thomas Aquinas in his famous fourfold classification of laws. In Christian theology the “law of nature” was regarded as the unrevealed law of God, implanted in the consciences of men—part of the light that lighteth every man that cometh into the world. The great Jesuit jurists of the sixteenth and seventeenth centuries—Mariana, Suarez, Bellarmin and the rest—adopted and developed the Thomist view. Now this conception of the law of nature as the unrevealed law of God—the mere appendix to the law revealed in the Scriptures and expanded in the canons of the church—was worse than useless to the international jurists. They needed a code that would be recognized as binding by Jews, Turks, infidels and even by South Sea savages. Grotius, therefore, although a sincerely pious man (of the Arminian persuasion), snatched the law of nature from the possession of the theologians and rationalized it, making it universal. It was, he said, the product of human reason: “*Jus naturale est dictatum rectae rationis.*” This was a revolutionary utterance, and it excited the fiercest antagonism of the despoiled divines. But it was so vitally important as laying the foundation of modern international law that the jurists maintained their possession against all the theological attempts at recovery.

In the Roman jurisprudence the *jus naturale* had been intimately associated with the *jus gentium*, i.e. the law of nature with the law of nations. Some of the great Roman lawyers, in fact, had gone so far as to identify the two, contending that the *jus naturale* is merely the abstract and philosophical presentation of the concrete and practical *jura gentium*. Grotius found this close association extremely serviceable to his purpose. Having appropriated the *jus naturale* as a principle of international morality, he adopted the *jus gentium* as a code of international custom. It provided him with countless invaluable rules concerning such difficult questions as the modes of acquiring property and the means of discharging obligations. It has been much debated whether or not he

was aware that he was taking a system of private law and converting it into a system of public law. Certainly he effected the great transmutation without drawing attention to it. But he was no fool, and it is best to assume that he knew what he was about.

His sense of the need of an authoritative body of international law independent of theology had been quickened by three great conflicts with which in his official capacity he had had to do. First, in the East Indies, the Dutch and the Portuguese had become involved in a furious struggle for markets and trading stations, in which no common standard of right had been recognized (1604). Secondly, in the North Sea and the English Channel, English and Dutch seamen had developed a fierce rivalry, the one contending that these waters were their exclusive property, the other maintaining the freedom of the ocean (1609). Finally the Thirty Years' War (1618–48), with its unprecedented tale of horrors and atrocities, brought home to Grotius the urgency of the demand for some laws of war and peace which both Protestants and Catholics, both Christians and infidels, would accept as restraints upon unmitigated barbarity.

In these circumstances he wrote his great book *De jure belli ac pacis* (1625). Compiled in exile in France, it is dedicated to Louis XIII. It contains prolegomena treating in general terms of the state and of law—a treatise of the highest interest and importance to students of political ideas. Then it proceeds (bk. i) to argue the question whether or not war is ever just, coming most emphatically to a positive conclusion. Next (bk. ii) it proceeds to enumerate and examine the just causes of war. Finally (bk. iii) Grotius lays down, on the basis of the *jus naturale* and the *jus gentium*, detailed rules for obviating the outbreak of war and for mitigating its abominations when once it has become kindled.

Few books have had a more powerful or a more beneficent influence upon the conduct of human affairs. All through the seventeenth, eighteenth and nineteenth centuries it operated to limit the scope of hostilities, to ban atrocities and to extend the humanities in war.

X. The ferment in men's minds caused by the Renaissance and the Reformation, by the new astronomy and the new geography, by the revival of humanism and the return to primitive Christianity, by the spread of science and the

manifestations of the Reformation era, viz., Andreae's *Christianopolis* (1619), Bacon's *New Atlantis* (1627), Campanella's *City of the Sun* (1637) and Harrington's *Oceana* (1656). Sir Thomas More's great romance, which gave its name to the whole series of imaginary commonwealths, is by far the finest and most illuminating of all. It relates especially to early Tudor England, but it depicts conditions that were common throughout western Christendom. It delineates in vivid colors (as they would appear to a visitor from a distant and very different land) the evils of the age and locality. It examines their causes, and enumerates them under the main headings of bad government, dishonest business, unjust and unwise finance, enclosure, sheep farming and, above all, the institution of private property. It does not directly prescribe remedies but, instead of doing so, describes the constitution of the remote island of Utopia where a better order of things prevails. That blissful island, it appears, is happy in community of property, an autocratic administration, state controlled family life, rigidly regulated and enforced public education, and religious toleration. The eminently conservative and Catholic Sir Thomas More by means of his brilliant flight of imagination let a large number of revolutionary ideas loose upon the world. It should be noted, however, that More's *Utopia*, like Plato's *Republic*, assumes the institution of slavery as its basis.

Andreae's *Christianopolis* is merely a Lutheran version of More's *Utopia* without the slavery and without the religious toleration. It is strictly sectarian in its organization; regular attendance at church is its primary regulation. Next to religion education is prominent. The material goods of life, which are possessed in common, seem to be plentiful; but whence they come does not appear.

Education, secondary in Andreae's *Christian-*

opolis, is primary in Bacon's *New Atlantis*. The interest in this rather dull and pedantic work centers in the picture which it presents of "Salomon's House," a great civic college where all the arts and sciences are investigated. Campanella's *City of the Sun* displays the idea of the mediaeval monastic organization—celibacy excepted—applied to the constitution of a model city-state. It is rigorously governed, on principles of poverty and frugality, by autocratic religious rulers. Labor is compulsory; its products are pooled; both property and wives are held in common; population is regulated by the authorities on strictly eugenic lines.

Harrington's *Oceana*, a long and labored fantasy, is important in the history of the social sciences as foreshadowing the economic interpretation of history. Harrington was a keen advocate of the doctrines of the sovereignty of the people and the natural equality of men. He perceived—and he was one of the first of moderns to do so—that true democratic equality is unattainable, or at any rate unmaintainable, in the presence of great inequalities of wealth. Hence in his *Oceana* the prevalence of equality is secured by periodical redistributions of land, coupled with an administrative system according to which (as in Periclean Athens) all citizens hold office in turn.

Harrington wrote during the period of the Protectorate of Oliver Cromwell in England. It was a period of tremendous vitality, full of conflict and controversy, amazingly rich in seminal ideas in all departments of social and political science. Even a cursory study of the pamphlet literature of the time makes it abundantly clear that there is scarcely any important conception which has molded the thought of the subsequent three centuries that is not in some shape or form anticipated by some speculator of this robust age.

VII

The Rise of Liberalism

I. If liberalism be defined as the attitude which tests the validity of behavior and of institutions in terms of the rational consent of men, it is permissible to regard it as the younger and unwanted child of the Reformation. Social philosophy is, indeed, always the offspring of history; and the stages of its development are unintelligible save in terms of the events out of which it took its rise. Every thinker who essays the task of interpreting the needs of men is, at bottom, writing his own autobiography. For what he recounts is an analysis of his own experience, his effort to make systematic the lessons he has learned from the facts about him. Of no period is this generalization more obviously true than of the seventeenth century. If the Reformation gave birth to the absolute state, the poison of its autocracy provided its successor with an effective antidote. For the absolute state was born of war and persecution; and meditation upon the price to be paid for its establishment drove men to the consideration of alternative philosophies.

The seventeenth century is, in an emphatic sense, an age of critical transition; and it was therefore natural that its manifold uncertainties should make it the birthplace of the liberal temper. If older dogmas still lingered on, they were examined anew and challenged. If older philosophies still asserted their prestige, their rivals displayed a new and ultimately victorious certitude. It is the age in which scientific method and experiment first secured their dominating hold over the minds of men. It is the age, also, in which men began slowly, doubtless, and with pain to test religious claims in terms of social cost; and therefrom to replace the theological foundations of political authority by principles more capable of a rationalist interpretation. It is, not least, the age in which the edifice of feudalism is recognizably in profound decay, and economic organization becomes the effective expression of a national policy conceived in the terms of what state power is held to demand.

These changes are evident in the seventeenth century; but it is important to remember the prelude to their emergence. The overthrow of

the mediaeval papacy provoked everywhere a widespread spirit of challenge and inquiry. New dogmas no sooner arose than the demand was made for their justification; new authority was no sooner proclaimed than its pretensions were ruthlessly examined. Novelty in the sixteenth century was so widespread and so various that the rational temper which is the root of liberalism was its logical and necessary outcome. Lutheranism had hardly created conditions for the rediscovery of the divine right of kings when the emergence of Calvinist sects, especially in France, Scotland and Holland, made necessary the doctrine of a social contract. Huguenot writers had hardly insisted upon the right of revolt in the nobility before the Catholic opponents of Henry IV had transferred that right to the people at large. The ink was scarcely dry upon the claims of Spain and Portugal to empire when England and France entered into the competition for the spoils of geographical discovery. The revival of classical learning had poured a new content into philosophic and religious speculation. The rise of mathematics in its modern form pushed supernatural hypothesis from the center to the circumference of thought. The birth of Biblical criticism combined with economic need to make the cost of persecution—the advantage, therefore, of a rational tolerance—seem increasingly obvious over a widespread area. And if the absolute prince was prepared to play the despot in the name of his private creed, men were forthwith prepared to inquire whether political power was not a trust, to be forfeited where it was betrayed. Without the passionate intellectual ferment of the sixteenth century, the liberalism of the seventeenth would hardly have been possible; certainly it would have been neither so widespread nor so creative. As it was, it developed naturally in a soil well prepared for its reception.

With the seventeenth century we emerge into a Europe which had replaced the mediaeval ideal of a single and unified Christian commonwealth by a system of independent and sovereign states, no one of which conceived itself as

owing duties to its neighbor. The consequences of this change can easily be underestimated. It meant not only the rejection of the temporal supremacy of Rome and with it the rejection of the moral outlook in politics of which Rome was the appointed guardian. It involved also a growth in the secular temper, a replacement of values conceived in terms of eternal spirit by values conceived in terms of earthly power. This made possible the development of an idea of progress, the rejection of the social consequences involved in the doctrine of original sin. For power was dependent upon the discovery of new truth; and new truth, in its turn, was the result of applying reason to the analysis of phenomena. Once that step had been taken, the evolution was natural, first, to the insistence that there are no limits to the empire of mind, and, second, to the inference that the growth of mind was also the growth of good. Once such an attitude was possible, it was clear that the claims of tradition and antiquity were assailable in their innermost citadel. We can, indeed, already see the beginnings of the challenge in the sixteenth century. The reputation of Galen was obviously undermined by the researches of Vesalius; Aristotle lost his mediaeval preeminence after the attacks of Cardan, Ramus and Bruno; Copernicus' attack on the cosmology of Ptolemy made necessary a new and unimagined theory of the universe. The epoch of the Reformation was well aware that it stood upon the threshold of gigantic discovery. Gargantua tells Pantagruel that the field of study is wider in his day than anything known to Plato or Cicero or Papignan; and Peter Ramus with his claim that "a single century has seen a greater advance than . . . in the whole course of fourteen previous centuries" bespeaks a temper in no sense mediaeval. Obviously enough the seventeenth century reaped the harvest its predecessor had sown.

What, in fact, was that sowing? There are three conditions of the inheritance upon which it is necessary briefly to dwell. Geographical discovery, continuous throughout the sixteenth century, gave a new spaciousness to the minds of men. It accustomed them to the ideas of novelty and diversity; it broke the cake of custom to which they had been used as nutriment. The social consequences of the discoveries were tremendous. They involved corporate enterprise instead of individual enterprise; and this, in its turn, made the machinery of the state a vital factor in the encouragement

and protection of trade. They meant, in the second place, a realization, infinitely more acute than in the past, that human habits were immeasurably more various than had been imagined; and this, in its turn, was not only a dissolvent of tradition, but also, as is evident from the utopias, a new basis for social idealism. From *Utopia* to *Télémaque* every romance bears witness to a new attitude to paganism; and the introduction of the noble savage into literature is nothing so much as a method of criticizing traditional social arrangements. It is not too much to say that no factor was more potent than geographical discovery in persuading men that institutions are by no means unchangeable and that the human will is itself a factor in the making of change. The discoveries, moreover, meant settlements and colonies, and in these it was rarely possible to maintain the more rigorous formalities of status habitual in the old world. As a consequence travelers' tales from the West are tales of men who rise above their station, and of religious differences that are forgotten or abolished in the union necessary for self-preservation. Nor must we omit the significance of the voyages as a factor in the triumph of rationalism. For their revelation of variety in social arrangements, economic not less than political, gave rise to the need for comparison between different principles; and here, once more, the power of tradition had slowly to give way before the need to convince the reason of men. The necessity of kingship, the power of a priesthood, the permanent division of society into rich and poor, appear less final than before to men who have been told that societies both exist and prosper in which no such principles are for a moment tolerated.

The new geographical world implies, then, at least slowly, a new social world. The same result follows from the impact of scientific discovery and philosophic system. The essential effect of the Copernican revolution was the withdrawal of cosmology from the field of revelation. It had become necessary to interpret the universe not in terms capable of being reconciled with traditional theology but in a manner consonant with observation and experiment. In the long run it is not improbable that the growth of science was more fatal to ecclesiastical pretensions than any other single influence. For it established an order of nature which not only contradicted received theological opinion but also demanded unlimited inquiry

as the condition of its own development. Once again, therefore, it made for the acceptance of novelty, and this, in its turn, meant the triumph of rationalism. Implied in that victory was the perception of the common sense of toleration; for heterodoxy in natural philosophy could only be penalized in terms of an arrest of knowledge. By displacing the earth as the center of the universe, the Copernicans, albeit only half consciously, displaced the theology which had sponsored the adequacy of the Ptolemaic system. In its place they put the principle of reason and thereby they dethroned the pretensions of the supernatural to be the residuary legatee of human ignorance. For when so much could be rationally explained in terms of the new scientific certitude; when so much newly explained meant the overthrow of what tradition had persuaded men to regard as ultimate; the acceptance of the supernatural as the source of hypotheses gave way in part to skepticism and in part also to a belief that the patient analysis of phenomena by the new methods would alone reveal to the mind secrets which had thus far defied its scrutiny.

This, at least, is the attitude which, in an incomplete and fragmentary way, the sixteenth century passed to its successor. It is worth while to emphasize in a little detail the use made of the inheritance. Broadly speaking, the canon of the new era was the necessity of a direct appeal to nature. Reason was to act upon the evidence of the senses, not as in the previous period after all authority had been exhausted, but as the only way in which an authoritative explanation is available. Laboring upon the foundations which Copernicus, Kepler and Tycho Brahe had laid, the seventeenth century may be said to have built, by the method of observation and experiment, a new material universe. With its details, of course, we are not concerned. But we must note that the new calculus of measurement permitted the formulation of laws which explained the action of every body in the universe. And what to the age seemed striking about those laws was their revelation of a universe capable of reduction to a strict mathematical interpretation. The natural thereby became identified with the rational; and the discoveries which culminated in Newton's laws seemed to set a model for every field of human inquiry. Guesswork, chance, tradition, were simply annihilated. A world came into view in which hypothesis became certitude by experimental verification.

And when to the triumphs of the method in the field of mechanics were added those of Torricelli and Pascal, of Boyle and Huyghens, it is not difficult to understand the intoxication of the century with its own achievement.

The philosophic significance of the new science, indeed, was perceived even before its experimental triumphs had been secured. With Giordano Bruno it had already led to a half-intuitive perception that in a universe so constituted Christian truth became an episode and a fragment, that a mystic pantheism free from historic dogma of every kind was the only religious consolation left to man. In Bacon it led to the sense that by the scrutiny of the secrets of nature man might obtain power over her for his own ends. Central to his thought are a complete contempt for what has gone before and a confidence that the method of experimental inquiry is the highroad to truth. Science for him has become definitely humanized. It is independent of all theological trappings and subservient to definitely practical ends. It is a secular instrument, asserting its own right to investigate because of the power it will attain through knowledge so revealed. That Bacon only imperfectly understood the significance of the new discoveries is doubtless true; but his sense of their bearing upon human destiny is, in its largest outline, both new and *far-reaching*. It will, he has no doubt, give *man* new dominion over nature; and in that authority, discoverable only by the careful scrutiny of natural processes, the source of his happiness will be found.

What Bacon clearly implied was the idea of progress; and with that implication there necessarily goes a tacit condemnation of the whole theologic structure. He did not, indeed, as his insistence that his epoch is the old age of humanity makes clear, fully understand the import of what he was struggling to say. He was in the new age, but not completely of it. The philosophy which first frees itself completely from the ancient moorings is Cartesianism; and without a grasp of the impact it made, the rise of a liberal doctrine is unintelligible. The significance of Descartes lies in the majesty of the claims he made for the new methodology even more than in the discoveries for which he was sponsor. By his insistence on the supremacy of reason he challenged the whole power of faith and tradition. By his affirmation that the laws of nature were unchanging he banished the idea of a presiding

Providence from the order they governed. Once the revolution these notions implied had come to maturity, the triumph of a secular world over a theological conception of the universe was inevitable. And maturity came as soon as the discoveries of the century seemed to affirm the truth of Cartesian hypotheses. There were then present all the solvents required for the final rejection of mediaevalism. To abolish Providence was to throw man back upon himself. To throw him back thus was to insist that reason must know no bounds to the empire it investigates. Once that is argued, the way lies open for the emergence of the liberal spirit; and with its emergence in the scientific field it was inevitable that it should make its way into matters of social constitution.

This does not, of course, mean that the new science triumphed quickly, or that the spirit it involved made its way easily into other realms. Puritanism in England was hardly conscious of its influence or, where it was conscious, was hostile; while the Jansenist movement in France, though its leaders avowed themselves Cartesians, was in effect inimical to the progress of the scientific attitude. The cause of its victory lies in a wide variety of fields. Partly the reason is to be found in the discredit religion brought upon itself. The excesses of Puritanism produced a reaction, and in that new atmosphere what triumphed was not the religious spirit, but deism, on the one hand, and toleration, on the other. In France the religious revival of the early seventeenth century did not endure; and the struggles between Jansenist and Jesuit, between Catholic and Huguenot, enormously increased the area of religious indifference. This, in its turn, opened the road to the confluence of certain critical tendencies of which the cumulative power was enormous. There was the inheritance from Rabelais and Montaigne of the belief that man finds himself in an obedience to his impulses which, by its genial epicureanism, is at once a protest against the ascetic discipline of the church, and a gospel of pleasure for pleasure's sake which makes reasonable choice, and not traditional pronouncement, the path to the good life. In the hands of men like Saint-Evremond the attractiveness of this doctrine became obvious; and it fitted in easily with the picture of the "honnête homme" so admirably incarnate in the aphorisms of La Rochefoucauld. There is the development, further, of religious rationalism. Deistic hypotheses made enormous

progress during the century. Lord Herbert of Cherbury, Hobbes and Selden in England, the *Libertins* in France, Spinoza in Holland are all of them evidence of how far the old orthodoxy had been undermined. John Spencer and Spinoza laid the foundations of the scientific treatment of Hebrew institutions. Richard Simon started the scientific study of the Old and New Testaments. When Bayle came to write his great dictionary he was attempting to build a structure of disbelief the foundations of which had already been planned.

In a sense nothing shows this more clearly than the change in the temper of religious defense. Apologetics in the hands of Chillingworth and Tillotson, even of Pascal and Bossuet, has an atmosphere of reasonableness about it far different from that of the previous century. The half-conscious influence of the Cartesian spirit is omnipresent; and the extent of its triumph is perhaps measurable by the rapid growth of deistic literature in England once the Licensing Act was repealed in 1694. It is to be seen, also, in the constant admission by the theologians of the time of the degree to which skepticism had penetrated among the multitude. The age, said Tillotson, is "miserably overrun with skepticism and infidelity"; and Bossuet's letter to Huet of 1678 is an avowal of an unbelief which he does not doubt is wider than at any previous time. Nor is it without significance that the most famous defense of the Christian faith in the seventeenth century—that of Pascal—should have been hardly less a grammar of skepticism than a justification of credence.

Science, philosophy and theology, therefore, all reveal in the seventeenth century the increasing permeation of the rationalist temper. They show a generation driven back to first principles, with the eternal result that the inheritance is transformed in the process of examination. What the seventeenth century commenced its successor completed. What had been moderate and half-hidden in the one became determined and decisive in the other. The eighteenth century in France and England is nothing so much as a determined onslaught upon revealed religion. The attack of Hume is its supreme intellectual expression; but Voltaire, Diderot, Holbach, to name only the outstanding critics, set the ecclesiastical phalanx permanently upon the defensive. The real achievement of the philosophic movement of the eighteenth century was to complete the case

for a purely secular conception of social life. Building upon the acceptance of the Newtonian universe, they made the literal interpretation of the Christian revelation impossible to intelligent men. And therefrom they drew the inference that if its theology was dubious its power was without justification. They denied altogether the sanctions it proposed to exercise in political and social life. They destroyed that alliance between church and state which had made the beliefs of men the test of their capacity for citizenship. By rendering at best dubious the adequacy of the beliefs themselves, they made of religion a private matter independent of the overt expression of conduct, and created a secular ethic with which alone, as it received outward form, it seemed legitimate for the state to concern itself. Naturally enough this victory of the utilitarian temper did not make its way with ease. The triumph of the Toleration Act must be set alongside the defeat implied in the revocation of the Edict of Nantes. But it is notable that the eighteenth century in England saw no effective revival of religious persecution; and if Calas and de la Barre were executed in France, the most striking element in their fate is the applause which greeted Voltaire's vindication of their names. By the time of the French Revolution men were able to think and to say things that before 1700 would undoubtedly have involved a ruthless persecution. They were able to do so because the ecclesiastical interpretation of life had ceased to occupy the center of the stage. Its view of the universe having been rejected, the principles of the new philosophy were applied to realms which had once been deemed its own empire. And until the revival of mediaevalism with the romantic movement, the claim of theology to a dominating place was not so much challenged as neglected by those who set the temper of men's thoughts.

II. Not, of course, that the scientific development and its consequences are independent of political and economic events. Anyone who seeks to explain the rise of liberalism must at least indicate its connection with new institutions in the world of practical life. In one sense, at least, the fundamental event of the seventeenth century is the emergence of the middle class into political significance. The Dutch Rebellion and the English Revolution are the two outstanding expressions of its power; but it is also important to remember that civil war

in France, in destroying the nobility as a political factor and making possible the centralized despotism of Louis xiv, left the monarch and the middle class face to face as soon as dissatisfaction should develop. The rise of the middle class is important because its economic needs required a type of liberty of which constitutionalism was by all odds the best expression. The middle class needed exactly the central principles of liberal doctrine if it was to prosper. It required religious toleration because the establishment of this principle was inextricably intertwined with the rights of property. It required limitation upon monarchical prerogative lest it be ruined by arbitrary taxation. It required a controlled aristocracy because the establishment of internal peace was the essential condition of commercial prosperity. It required the abrogation of the mediaeval theories of restrictive regulation in the interest of morality because in such terms individual enterprise could not reach its maximum fruition. The new economic order, in a word, required a secular state; and a secular state, in its turn, required a liberalizing doctrine if politics was to be more than a branch of theology. What the scientific revolution had begun the utilitarian revolution completed. Right gave way before the claims of expediency. A state was built which corresponded to the wants of the new men to whom power had flowed.

It is worth while to dwell for a moment upon the ideological significance of the three great political events of the seventeenth century. The successful establishment of the Dutch Republic was the first organized invasion of the monarchical principle in the modern world. It was a success which came in the name of religious toleration and the right of a nation to determine its own destiny. It offered immediate proof that its basic principle was the parent of religious toleration; and its permanence was a victory not only for constitutionalism against autocratic government but also for the independent and sovereign state as the form in which the exclusiveness of nationalism seeks naturally to clothe itself. The English Revolution, in which the final synthesis of 1689 is only the culmination of a movement lasting some fifty years, brings with it not only religious toleration and constitutional government (both of them, as in Holland, the parent of commercial prosperity), but also the creation of a parliamentary system the implications of which

change the whole substance of political philosophy. There is even a sense in which the despotism of Louis XIV may be said to have enforced upon men's minds the belief that the constitutionalism of England and Holland was of superior validity as a governmental system. For after 1685 it was no longer accepted as other than a system in decay. The ruin it had produced was not only obvious, but in striking contrast to the prosperity of its rivals. Saint-Simon, Fénelon, Vauban, Boisguillebert, all point the lesson that in some fashion the arbitrary exercise of power is incompatible with the attainment of social good. Their successors among the *encyclopédistes* of the eighteenth century are occupied in nothing so much as the conversion of public opinion to that view. They were successful in their effort; but the *malaise* of the monarchy was too deep to make peaceful reformation possible. The failure of French liberalism in the seventeenth century to secure institutional expression is the essential cause of the breakdown in 1789.

Nor must we forget the influence upon social institutions of the breakdown of the mediaeval economic organization. A new economic imperialism destroyed the old supremacy of the eastern market; and with its coming the scepter of trade passed from Venice and the south German cities to the states of the Atlantic seaboard. Capitalist enterprise, especially in textiles and in mining, made impossible both by its extent and power the retention of ancient regulation. Commercial companies discovered in the use of the state prerogative methods of legal organization which were revolutionary in their significance. A financial technique was evolved which synchronized with both the collapse of rural social categories and a catastrophic change in the price system. By the middle of the seventeenth century the economic world was characterized by all the main features which distinguished it until the application of steam power to industry. The wants of the new economic order were incompatible with the mediaeval notions of fixity and status. The new markets demanded enterprise; the new factories demanded free labor. Religious opinion, not less than political philosophy, adapted itself with remarkable swiftness to the wants of a new world. They accommodated themselves to a conception of life in which the possession of property was the mark of virtue. They preached a gospel of work in which poverty became the expression of nothing so much as the disfavor

of God. That nature which, in the Middle Ages, had been the reflection of the Divine Will, became in the seventeenth century the response to human appetite—an appetite, moreover, freed by the new individualism from the restrictions of the earlier time. The development was rendered easy by the compromise effected by Calvin in his discussion of the problem of interest. Once the mediaeval ban on usury was lifted, religious precept was necessarily harnessed to the new institutions. The churches practically abandoned their obligation to formulate a social doctrine which should insist upon man's duty to his neighbor. When it could be plainly said that "it was not in simple divines to show what contract is lawful and what is not," it is obvious that the basis of economic arrangements had ceased to be theological and had become utilitarian. The Reformation and its aftermath had already shown how profound was the resentment of ecclesiastical discipline in the field of social policy; and whatever lip service was paid in the seventeenth century disappeared after the Puritan rebellion in England, and the reduction of the church in France to a pliant instrument of administrative purpose. Thenceforward the way was directly open to the idea of free contract as the basis of society; and with its emergence a purely secular standard of social values could prevail. Economic liberalism was the heir of the church's failure to understand the part it might play in the new world. An acquisitive society won the opportunity for unfettered development as soon as the church ceased to play the part of the critic entitled to test the moral adequacy of human effort and human institutions.

III. Political philosophy in the seventeenth century is, for the most part, English where it is important; the continent had no names to set alongside those of Hobbes and Locke. In Althusius, indeed, the impact of Dutch achievement and experience gave birth to theories of ample profundity; but there is little evidence to show that he deeply or widely affected the minds of men. The seventeenth century was mainly English because the prevalence of ruinous civil war upon the continent hardly left men space to do more than sigh for peace; and the relief at its coming was everywhere so great that, with rare exceptions, even an autocracy like that of Louis XIV was acceptable because it brought with it the cessation of conflict. But in England, until the last ten years of the century,

foreign war was an incident which hardly affected the substance of the national life; and the matter of internal conflict was such that the debate was bound to center about the fundamental problems of politics.

That is, indeed, obvious from the outset of the century. Already in Bacon, if we have a theory that is ultimately absolutist in temper, its whole basis is essentially utilitarian; and if he finds therein a place for the church, it is as no more than an effective instrument for the development of a state power conceived in purely secular terms. Even religious speculation may be said to have advanced the power of the secular state. For when the Church of England allied itself with the monarchy in the hope of destroying Puritanism it virtually abolished itself as an independent political authority; and the partnership of the Puritans with constitutional and radical theories hastened both the victory of Parliament and the advent of toleration. The lawyers, also, were a force in promoting the decline of ecclesiastical authority. For they not only attacked the desire of the church to be the inheritor of the religious courts, but they also provided the legal theories out of which the structure of the new state could be determined. Puritanism, also, acted necessarily as a dissolvent of mediaeval tradition. Since most of its devotees were to be found in the middle classes, it was inevitable that they should resent a state which, by persecution, interfered with their commercial effort and the prosperity of the country. They drew from their experience of its activities a bias against state action; and the liberal faith in a state whose interference is at a minimum is deeply rooted in nonconformist traditions. Puritan, also, may be said to be the dogma of equality in English political philosophy. Men like Lilburne and Rainsborough and Winstanley are the expression of the victorious spirit of a class which sees in the abrogation of special privilege the guarantees of its own well-being. The doctrine was premature as a philosophy because it failed to correspond to the distribution of economic power. The revolution that actually came was, as Harrington so magisterially perceived, essentially, in its final form, the constitutional expression of the new economic order which the previous hundred years had brought into being. A negative state, parliamentary government and toleration were all that the new class desired; and more radical theories, to which the disillusion of a revolutionary period natur-

ally gave birth, had to wait for a more ample realization.

The most significant figure in the first part of the seventeenth century is Thomas Hobbes (1588-1679), in sheer intellectual power the most eminent name in English political philosophy. To understand at once his place in the mind of the century, and the import of his doctrine, we must realize, first of all, the significance of his intellectual contacts. He represents, with all his errors and inadequacies, the "natural philosophy" of the seventeenth century in the fullest sense of that term. Few men have specialized so profoundly in omniscience. Physicist, geometer, psychologist, metaphysician, Biblical critic, social theorist, there is hardly any department of human knowledge which was not swept into the generous ambit of his system. The friend of Galileo, the secretary of Bacon, the intimate of Mersenne and the Cartesian society of Paris, he was in close communion with the advanced scientific outlook of his time. He represents the first systematic attempt in English philosophy to erect a theory of the state upon foundations altogether independent of theological principle. Whatever the burden of his conclusions, the temper in which he worked was essentially what the new liberal outlook required. He is consistently rationalist, consistently utilitarian, consistently Erastian. He was fundamentally materialist and, in essence, utterly hostile to supernatural hypotheses in the realm of social thought. Both his ethic and his psychology show how completely possible it had already become for their principles to be worked out upon a basis entirely secular in character. If Hobbes' political philosophy is, *de Maistre* apart, the most powerful plea for autocracy that has ever been made, it is a plea built upon the assumption that every state is a completely self-sufficient organism which does not need to look outside itself for the sanctions of its conduct. That, perhaps above all, was the thesis of which the new order stood most in need.

Though Hobbes himself always insisted that his social philosophy was an integral part of his general metaphysic, it is no injustice to him to relate its emphasis directly to the events amid which he moved. He had seen the failure of the gunpowder plot; he was in Paris when Henry IV fell a victim to the dagger of Ravallac; he witnessed the "hot gossiping" which accompanied the beginning and the end of the civil wars. The fact that his work was the product of

a timid temperament, writing when a strong and stable government was sought above all things, justifies our seeing in it the fruit of personal experience rather than literary influence. Machiavelli and Bodin, Barclay and Bacon, he doubtless knew and profited by; but the reader of his political writings will hardly fail to realize that, even more, he was the shrewd observer of Pym and Richelieu, of Strafford and of Cromwell. In no writer of the period, indeed, is the lesson rough hewn from vivid contact with men more obviously set down. The problem he set himself is how to make a common life for men whose actions are always born of fear and self-interest. He posits a state of nature, after the fashion of his age, but it is a grim enough condition, a state of anarchy in which every man's hand is against his neighbor, and in which the lust for power destroys all security. He does not spare the details of his picture. "Continual fear and danger of violent death . . . no propriety, no dominion . . . but only that to be every man's that he can get and for so long as he can keep it." In such a condition men may be taken as broadly equal in their faculties since, in the absence of a recognized power of control, no man has mind or bodily strength enough to be free from the art or sudden violence of his fellows. From so dismal a world the one object of life must be the organization of release.

And the means of release are to be had. For if man is avaricious of power he also fears death; he desires comfort, he searches for security. Reason therefore suggests to him some form of agreement whereby peace may be attained. Reason urges him to leave the state of nature and thus gives him a law which we may term a law of nature in the sense that it is a precept of reason; but it is not a law of nature in the accepted sense. The law of nature is the power of man to do in the state of nature whatever he thinks fit. Included in it, indeed, are precepts which reason commands for the sake of self-preservation; and these, in their totality, are something akin to the moral law. But they are pointless enough in the state of nature, since there is no common authority to enforce them. This law of nature may bind us in reason, even in the pre-social state, since the rule not to do to another what you would not have done to you is the clear road to self-preservation. But it is, there at least, a rule without a sanction. It gains authority only by being applied; and a civil state is needed for its application.

Hobbes therefore assumes the making of a

covenant between men such that all surrender their natural rights to a sovereign, either by institution or by force. They then owe to this sovereign—be he a one or a many—an allegiance that is absolute and entire. This sovereign owes no duties to his subjects, while they are bound to one another to obey his commands. If, indeed, protection from insecurity does not result from the relationship, the subject is entitled to the resumption of his natural rights. But even then he has no remedy against the sovereign (since the latter owes no duty to him) and he resumes them at his own risk (since he has broken the contract with his fellows). He assumes, then, a sovereign power which, once established, is unlimited in extent; and the form of government can make no difference to its absolutism. Law is then simply a command of the sovereign, enforced by the sanction he institutes; and since there is no limit to the sovereign's power there is no such thing as an unjust command and, by inference, as an unjust law. As between different states Hobbes insists that there can be no condition save one of mutual distrust; "the law of nations," he writes, "and the law of nature is the same thing." But the weakness of the law of nature has been the absence of a common superior to enforce it; and the law of nations must, similarly, mean no more than the right of each state to do the best for itself that it can. A vital future lay before this rigorous positivism. .

We have thus a state in which, for the preservation of peace, a sovereign has been instituted with unlimited authority to impose his commands. Hobbes is insistent not only that a monarchical system is the best form of state but also that all others are in truth a mere perversion of it; "other governments," he writes, "were compacted by the artifice of men out of the ashes of monarchy after it had been ruined by seditions." His case for monarchy is urged with singular vehemence; it may be that the fate of Charles I and the position of Cromwell made his sentences even more biting than was customary with him. A monarch's interest, he says, is necessarily one with the public interest. He can get all necessary counsel, and that in secrecy; he is less liable to the inconstancy and faction which attend the sovereignty of an assembly of men. The evils to be expected from favoritism seem to him less than in the case of an assembly "where all will play this game on the principle of *hodie mihi, cras tibi*." Nor does he see more than temporary

inconvenience in the problem of the succession. He preaches the necessity for the strict control of churches by the state in passages of extraordinary power; and the need for the destruction of voluntary bodies is asserted by likening them to "worms within the entrails of a natural man."

Hobbes' thesis is, then, clear enough. The evil nature of man makes peace impossible without restraint, and the more concentrated the power exerted over him, the more successful that restraint is likely to be. The liberty left to the individual is twofold. He may do whatever the law does not prohibit; and he may even break the law since what binds him to obedience is simply the fear of punishment. But because the object of the state is security, Hobbes admits what for him is almost a legal right of disobedience in certain cases. Reason, he says, does not permit us to suppose that a man can be bound to kill or maim himself, or to be compelled to self-incrimination; nor is he bound to kill others or perform work of a dangerous kind; and whenever—a notable concession born, obviously, of the times—the sovereign is unable to give the protection for which the state is made, man resumes his natural rights. What, broadly, he has set out to do is construct a theory of social organization in which the radical doctrine of a contract is turned to the service of despotism. He has been so impressed by the conflicts of the previous century that he searches for a technique of order, whatever cost to individual freedom its institution may cause. So overwhelmed is he by the price of anarchy that he is not even prepared to pay tribute—as Filmer indignantly noted—to the fashionable doctrine of legitimacy. There is nothing about divine right in Hobbes, whether in the secular or ecclesiastical realm, except by way of contempt; there is nothing, either, about the rights of conscience except their danger. He had clearly no patience with Grotius' effort to regulate by accepted moral precept the practises of states; "covenants of government," he said, "without power of coercion are no security." He had no confidence in any power but the sword, no belief in any motives save the meanest in human nature. All that he asked for was a sovereign—whether Charles I or Cromwell was immaterial—who could force men to keep the peace. The state was thus, for him, concerned not with social good but with the condition upon which all human welfare depends; it was a restraint, evil, it might be,

but necessary upon men's appetites. The form he gave to his argument cut away the ground from under the feet of his opponents. Granted his premise—and it is difficult to see how a Calvinist, for instance, could deny his premise—and his conclusion followed with irresistible logic. He represents at its maximum that intense desire for a strong authority, impregnable both within and without, which was natural in his time. And his sense of the state as the sovereign legislator which could brook no rival, whose will was law because no will was superior to itself, was destined to play a fundamental part in future political philosophy. From Hobbes to Rousseau and therefrom to Hegel, on the one hand, and, on the other, to Bentham and thence to Austin, was but a step; and when that step was taken the theory of the state was finally redeemed from all possible contact with alien principles.

IV. In a sense, however, Hobbes had come too late; a theory of autocracy did not suit a generation which wanted, indeed, order, but an order compatible with individual freedom. How profound was that want is evident from the rapidity with which England recovered from the sense of shock administered by the Cromwellian regime. The legitimate king was restored, but he, not less than his people, recognized that he had been restored upon terms. The debate between 1660 and 1689 is about nothing so much as the terms of the constitution; both parties had to recognize that a constitution was inevitable. When the brief reign of James II seemed to imply a monarchical experiment outside the limits for which men were prepared, the invitation to William of Orange followed at once. Its consequence was a king who reigned by parliamentary title upon conditions set out in the clauses of statute. The Revolution of 1688 led straight to the Bill of Rights and the Act of Settlement. The dependence of the crown upon Parliament was established; the Nonconformists were rewarded with a partial measure of toleration; the development of the Bank of England and the party system set the seal of finality upon the new system. In all this was implied dogma incompatible with the rigorous theorizing of Hobbes. It needed a more mediating philosophy if innovations so striking were to be put in the framework of doctrine.

The theorist of the revolution was Locke; and he did not conceal either from himself or

from his readers the purpose of his effort. It was the intent of the *Two Treatises on Government*, as he said, "to establish the throne of our great Restorer, our present King William, and make good his title in the consent of the people." What he sought was a theory of the state which would justify exactly the principles of the revolution settlement. He had to show that there were limits beyond which the sovereign power could not be permitted to go. He had to explain how a state might be built in which the share of the people in power, the maintenance, therefore, of their rights in form of law, was definitely established. He had to justify a solution of the religious problem which maintained such variety of outlook as was compatible with necessary political unity. He had to build a polity which left unfettered the individualism of the new economic order. He had, in a word, to build an alternative to the Hobbesian philosophy; and to do that, as he saw, it was necessary to go back to the foundations of the state. Locke, it may be, lacked altogether the clarity and the relentless logic of his great predecessor; and he had little of that genius for compressing into a phrase the experience of a lifetime which makes Burke the one classic in English politics who can still be read with delight. But he saw with unsurpassed common sense that the main problem of his time was such a theory of the state as would justify the maintenance of freedom in terms of individual good. What he had to do he accomplished with such mastery that for seventy years he remained the outstanding expression of political liberalism; and not until the advent of Rousseau did the philosophy of the state take a new direction.

Why, asks Locke, does political power, "a right of making laws and penalties of death, and consequently all lesser penalties," exist? It can only be for the public benefit, and his inquiry is thus a study of the grounds of political obedience. Locke thus traverses the territory Hobbes had covered in the *Leviathan*, though he rejects every premise of the earlier thinker. The state of nature is, for him, governed by the law of nature. The law of nature is not, as Hobbes had made it, the antithesis of real law, but rather its condition precedent. It is a body of rules which governs, at all times and at all places, the conduct of men. Its arbiter is reason and in the natural state reason shows us that all men are equal. From this equality are born men's natural rights which Locke, like the independents in the Puritan revolution,

identifies with life, liberty and property. Clearly, as Hobbes had also granted, the instinct to self-preservation is the deepest of human instincts. By liberty Locke means the right of the individual to follow his own bent, granted only his observance of the law of nature. Property Locke derives from a primitive communism which becomes transmuted into individual ownership whenever man has "mixed" his labor with some object. This labor theory of value, it may be remarked, lived to become, in the hands of Hodgskin and Thompson, the parent of modern socialism.

The state of nature is thus, in contrast to the view of Hobbes, preeminently social. There may be violence or war, but this is only when men abandon that rule of reason inherent in their character. But the state of nature is not a civil state. There is no common superior to enforce the law of nature; each man, as best he may, works out his own interpretation of it. But because the intelligences of men are different, the law of nature is differently interpreted. Uncertainty and chaos result, and means of escape become necessary from a condition which human weakness would make intolerable. It is here that the social contract emerges; and just as Locke's natural state implies a natural man utterly antithetic to Hobbes' gloomy picture, so does his social contract represent the triumph of reason rather than of hard necessity. It is a contract of each with all, a surrender by the individual of his personal right to fulfil the commands of the law of nature in return for the guarantee that his rights as nature ordains them—life and liberty and property—will be preserved. The contract is thus not general, as with Hobbes, but limited and specific in character. It is not, as Hobbes made it, the resignation of absolute power to the hands of an irresponsible sovereign. It is simply a contract of the members of the community with themselves to form a whole which thus becomes that common political superior—the state—which is to enforce the law of nature and punish infractions of it. Nor is Locke's state a sovereign state: the word "sovereignty," significantly enough, does not occur throughout the treatises. It is a state in which the minority agrees to be bound by the will of the majority for certain defined ends; but its province ends when its action passes beyond those boundaries.

Locke will have no truck with absolute power; and he has no patience with the divine right of kings. He dislikes oligarchy, because it

inevitably emphasizes the interest of a group against the superior interest of the community as a whole. Democracy alone offers adequate safeguards of an enduring good rule; a democracy, that is, which is in the hands of delegates controlled by popular election. He did not like republicanism; experience, doubtless, of the Puritan epoch had taught him that its disadvantages were serious. He was content to have a kingship divested of legislative power so long as hereditary succession and the making of laws were deemed to be dependent upon popular consent. The making of law, the formulation, that is, of the rules by which life, liberty and property are to be secured, is legislation and this, from the terms of the original contract, was the supreme function of the state. The legislature was to be bound by its own prescriptions; and the executive—in his view, a body of minor importance—was simply there to carry out its will. For him, at the back of each governmental act there is an active citizen body occupied in judging it with single-minded reference to the law of nature and their own natural rights.

There is thus a standard of right and wrong superior to all powers within the state. "A government," he wrote, "is not free to do as it please . . . the law of nature stands as an eternal rule to all men, legislators as well as others." The social contract is thus secreted in the interstices of statutes, and its corollary is the right of revolution. For to deny that right was to justify the worst demands of James II. "The true remedy," he said, "of force without authority is to oppose force to it! Let authority but step outside the powers derived from the social contract and resistance becomes a natural right; the state of nature supervenes, and a new contract may be made for which there is more hope of observance." Here, also, Locke takes occasion to deny the central thesis of Hobbes that since power must be absolute, there can be no such thing as usurpation by the sovereign. But Locke retorts that absolute government is no government at all, since it proceeds by caprice instead of reason; and he argues that it is comparable only to a state of war since it implies the absence of judgment on the use of power. It is wanting in the essential and continuing element of consent, without which no law imposes obligation. All government, for him, is a moral trust, and the idea of limitation is implied therein. But an unenforceable limitation would be worthless, and revolution remains

as the reserve power in society. The only hindrance Locke suggests is that of number; revolution should not, he urges, be the act of a minority. For the contract is the action of the major portion of the people, and its consent should likewise obtain to the dissolution of the covenant.

The problem of church and state demanded a separate discussion; and it is difficult not to feel that the great *Letter on Toleration* is the noblest of all his utterances. Not, indeed, that it stands alone; for it came as the climax to a long evolution of opinion and experiment in which the moral rightness and political adequacy of intolerance had been attacked on every hand. But Locke covered the whole ground, and it is notable that his outlook is built upon a denial that any element of theocratic government can claim political validity. The magistrate is concerned only with the preservation of social peace and does not deal with the problem of men's souls. He is entitled to suppress where opinions are entertained either subversive of the state or destructive of peace; though even here Locke thought that force was the worst of remedies. In England he was prepared, on these grounds, to deny toleration to Catholics, atheists and Mohammedans. The first, he thought, deny to others the rights they seek themselves, and they owe their essential allegiance to a foreign power. Mohammedan morals are incompatible with the civil systems of Europe; and there is absent from atheism—Bayle had just shown the contrary—the only satisfactory criterion of good conduct.

Though church and state are thus distinct they act for a reciprocal benefit; and it is thus important to see why Locke insists on the invalidity of persecution. For the cure of souls, he argues, the magistrate has no divine legation. He cannot, on other grounds, use force since it does not produce internal conviction. But even if it did, force would still be mistaken. The majority of the world is not Christian, yet it would, if force were legitimate, have the right to persecute in the belief that it was possessed of truth. Nor can he accept the implication that the magistrate has the keys of heaven. "No religion," he says finely, "which I believe not to be true can be either true or profitable for me." He thus makes of a church merely a voluntary society with no power save over its members. It may use its own ceremonies, but it cannot impose them on the unwilling;

and since persecution is alien to the spirit of Christ, exclusion from membership must be the limit of ecclesiastical power. Nor must we forget the advantages of toleration. It leaves the mind and actions of men unfettered; its eldest child is charity; without it there is no honesty of opinion. Later controversy did not make him modify these principles; and in the hands of his successors in England and France they became a vital argument for the completion of the secular state.

If there is little in the different elements of Locke's doctrine for which originality can be claimed, the synthesis itself was new, and the rapidity of its acceptance shows how welcome was its liberal temper to its generation. What opposition there was, was but the eddies of a stream fast burying itself in the sands. As early as 1693 Bayle could write that Locke has become the "Gospel of the Protestants." French Huguenots and the Dutch drew naturally upon so happy a defender; and Barbeyrac, in the translation of Pufendorf which he published in 1706, cites no writer as frequently as Locke. Addison, on six separate occasions, speaks of him in the *Spectator* as one whose possession is a national glory; and Swift softened his hatred of the malignant Whigs to find the epithet "judicious" for the man who was their master. He was, said Warburton, "the honor of his age and the instructor of the future." The eulogy is not too strong; for English political theory until the time of Hume is little other than a variation upon his central theme. Montesquieu paid him tribute when he made the separation of powers the keystone of his own more splendid arch. The teaching of Rousseau is only a broadening of the channel dug by Locke; no element integral to the *Second Treatise* is absent from the *Social Contract*. Rousseau, indeed, in many aspects saw deeper than his predecessor. He understood the organic element in the state, where Locke was still trammled by the bonds of his narrow individualism. Yet it would not be difficult to argue that Rousseau's theory is at no other point a real advance. The general will, in practical instead of semi-mystic terms, really means the welfare of the community as a whole; and for both the active consent of the individual citizen remains the central problem. Most of the difference between them, perhaps, lies in their historic position: Locke was justifying a revolution that had happened, Rousseau was to justify a revolution that had still to come.

It is this revolutionary element in Locke that gave him his significance in both the American and the French Revolutions. He laid down the essential thesis of liberalism that no government can ever be justified unless it draws its strength from the free consent of the governed. He argued that an invasion of reasonable claims makes legitimate a resort to force for the overthrow of the invading authority. That also is the essential claim of the Declaration of Independence; and the verbal resemblances between that document and the *Second Treatise* show how deeply Jefferson had drunk from the Lockian fountain. There was, indeed, reason and to spare for the irritable insistence of Dean Tucker that "the Americans have made the maxims of Locke the ground of the present war," and his jibe that Locke was "the idol of the Levellers of England," Price and Priestley, is true both of America and of France. For Locke is written large in the American bills of rights; and these, in their turn, were to be the principles of 1789. What Locke had sought to do was the effort also of liberals in America and France. He tried to construct a system of government which made it lie at the service of individual citizens. He, like them, was jealous lest it invade territory for the control of which he deemed it unsuited. He, like them, made individual consent, a vigilant citizen body, a limited executive, a separation of powers, the true bases of the state. It is not too much to claim that their triumph was his also.

V. It was not to be expected that the success of Locke in England would be paralleled upon the continent in his own lifetime, for the necessary institutions were wanting there. After 1614 the Estates-General did not meet again until 1789; and the *parlement* of Paris was a purely selfish legal corporation without real vision of a communal purpose. In both France and Germany, moreover, the combination of defective popular institutions and war was sufficient to make the need of a strong and centralized power more effective than the need for liberalism. What men ask for is a monarch who can rule, the cessation of civil strife, freedom from the heavy burden of taxation, relief from administrative oppression. In the vast pamphlet literature of the Fronde there are not half a dozen writers who seek any radical remedy; and even of these Claude Joly is the only one who has a system of any kind to recommend. The same conclusion is broadly true of Ger-

many. With the exception of Pufendorf, none of her political thinkers rises above a commonplace level. They are occupied either with merely legal technicalities or with the facile proof that monarchy is the best form of government. Even Leibnitz, for all his emancipation from authoritarian dogmatism, offers us little beyond a skilful defense, in the manner of Grotius and with no advance upon his matter, of the validity of natural law.

But the evolution of French political thought in the seventeenth century is significant. It has an official and a critical side. On the one hand are Richelieu and Bossuet, the one the outstanding architect, the other the supreme apologist, of the renovated monarchy; on the other are those—Jurieu and Bayle among the Protestants, Vauban among the officials, Fénelon among the clergy, Saint-Simon among the nobles—who ventured upon expression of their dissatisfaction with the regime. There is little in their argument that can be called at all justifiably a liberal doctrine. But the mood they represented, when linked with the inspiration that Voltaire and the *encyclopédistes* drew from Locke and England, and fanned by the new skepticism which grew from the union of naturalism, as in Saint-Evremond, and the claims of science, as in Fontenelle, became, with the decay of the monarchy in the eighteenth century, the distinctly French liberalism of which Voltaire and Montesquieu are the most important representatives.

Richelieu was a political philosopher indirectly only; the *Testament* and the *Maximes* are rather the acute reflections of a statesman upon his art than the expression of a coherent system. He represents, essentially, the supreme organizer who has come to restore order, whatever the cost of its imposition. Authority is to know no bounds, and disobedience is to be identified with sin. The prince, for him, is the state; to multiply the number of pilots is to ruin the possibility of a safe voyage. He insists upon the necessity of a rigorous but carefully masked control of the church; its doctrine may be left unfettered only so long as it does not impinge upon temporal power. Neither political assemblies nor corporations should be permitted in the state, for these represent a possible counterpoise to royal authority. Nor does Richelieu approve of municipal privilege; communities, he argues, never understand their own interests since “dans une communauté le nombre des folz est plus grand que celui des sages.” He does

not even hold with the supremacy of the courts in the purely judicial realm, but urges the need for extraordinary commissions to supplement, by royal prerogative, the inadequacies of judicial justice. The whole keynote of his theme is *raison d'état*; in matters so complex as those of politics, he argues in effect, attention to definite principles of action is impossible. He is not even deeply interested in the prosperity of the people; a little misery, he thinks, will keep their minds from wandering into the political realm. He has no use for the aristocracy, except as the basis of the armed forces of the state. The whole is a sinister picture of a man avid for power and careless of, even uninterested in, the methods by which it is maintained.

The explanation, of course, is a simple one. No powerful and ambitious man could have passed through the experience of religious and civil war without insisting that the only path to safety lay in the presence of a Machiavellian prince at the helm of state. He wrote of what he had himself achieved; and the years of Louis XIV's minority are an apt commentary on why his views shaped themselves as they did. The wars of the Fronde stand out in singular contrast to the contemporaneous civil wars in England. They were purely factional fights of selfish minorities seeking to profit themselves from the feebleness of an incompetent regency. They produced no great leader and no great thinker. In the several thousand *Mazarinades* there are not half a dozen which express more than the misery or the passion of the moment. Only Claude Joly, as the wars came to a close in 1652, showed some power of insight into the principles of government. He at least sees that all power must rest upon a popular origin and that there can be therefore neither a divine right of kings nor an unlimited royal authority. Kings exist for the good of their peoples, and tyranny implies a right of resistance. Joly sees, too, the importance of individual liberty; and his detailed condemnation of Richelieu's judicial methods shows that he holds firmly, as befits the grandson of Loisel, by the supremacy of fundamental law. He demands a meeting of the Estates-General, and refuses to admit a right of taxation without its consent. Nor, in his judgment, has the king the power to make law without the consent of the constituted magistracy of the realm; and this must be given without the exercise of undue pressure. He urges, finally, that no war should be made except as a last resort and then only after the

king has taken counsel with the Estates of the kingdom.

Here, at least in outline, is such a liberal program as neither Pym nor Hampden in England would have rejected. But it came too late. There were neither the leaders to advocate, nor the institutions through which to work, its possibilities. When Louis XIV began his personal rule in 1660, the stage was already set for centralized despotism. Louis himself was intent upon the fullest possible exercise of his prerogative; and the unintelligent memoirs that he composed for the instruction of his son reveal a mind in which the hypothesis of divine right had assumed axiomatic form. Contemporary theory in France, at least, had no creative alternative to propound. The textbook writers, Priézac, Scudéry and the rest, all repeat the ornate commonplaces which, as in the reflections made for Sir Thomas Elyot, did duty in sixteenth century England for political wisdom. It was not until the advent of Bossuet that an attempt was made to give the Augustan autocracy a theoretical foundation.

Few writers on politics have received panegyrics so splendid as Bossuet; few also have done so little to deserve them. At bottom his political philosophy is little more than the conclusions of Hobbes loosely set in a theological context which he did not realize to be already obsolete. The magnificent eloquence, indeed, serves often to conceal the poverty of the thought; and the reality of the learning in which the conclusions are clothed often gives them the air of being a system of rigorous inferences from the accumulated wisdom of the ages. But what, in sober fact, has Bossuet to say? Like Hobbes he draws a grim picture of an evil state of nature from the anarchy of which men are only too glad to escape. Like Hobbes, also, he insists that absolute power alone could end so terrible a condition. With his English predecessor he concludes that the rights of the subject are no more than a concession from the sovereign power, and that monarchy, which best assures peace and order, is by far the best form of government.

Here, at least, is nothing of novelty. It is true enough that Bossuet, unlike Hobbes, sets his conclusions in the background of a philosophy of history which, built upon the theses of St. Augustine, makes Providence the master of historic events. It is true also that the principles of his *Politique tirée de l'Écriture Sainte* are made to depend upon the support

of Scriptural texts. But the foundations of his system are in fact mostly independent of all theological apparatus. The unity of a people is dependent on sovereignty being invested in an absolute prince whose power is of God: "the royal throne," he says, "is not the throne of a man but of God Himself." All government is entitled to respect, and revolt is the antithesis of the spirit of Christianity. No citizen has any right to attack the public power; and therefore even the prince who does evil must be obeyed. He denies altogether the contractual origin of political authority, and makes prescription the basis of a title however brutal its origin. Popular government, for him, is always the parent of tyranny; and the freedom of the individual means in the end popular government. Kings therefore are absolute, since without such power they cannot fulfil the purpose of authority. To be absolute, indeed, is not to be arbitrary; the king should obey those fundamental laws which are built on equity and right reason. Freedom of the person and property deserve respect; and the king must make the care of his people his first obligation. But he is himself the sole judge of how and when his obligation should be performed.

It is not difficult to see beneath the mask of Bossuet's seeming abstractions a system of generalizations from the events of his time. His state of nature is the wars of the Fronde; his people as the tyrant are the Puritans under Cromwell; his king who acts as father, under God, to his subjects is the professional eulogy of Louis XIV. As a philosophy it might well have succeeded had prosperity attended upon Louis' effort. But defeat abroad and misery and intolerance at home combined to evoke a protest against its assumptions which provided the foundation for the emergence of liberal ideas. The Huguenot pastor Jurieu proclaimed, if in exile, the right of the people to cashier an evil ruler, and insisted that its sovereignty is the only legitimate basis of political power. Bayle was only the most learned and able of a score of writers who made the case for religious toleration with a width and insight that not even Locke surpassed. Vauban and Boisguillebert exposed, in merciless detail, the ruin wrought by Louis' disastrous policy; and though the fiscal remedies they had to propose were timidly incomplete because they lacked a sound institutional scheme to give them effectiveness, at least they showed that men were prepared for innovation.

The diaries and projects of Saint-Simon reveal that even at the center of the aristocracy the grim despotism of Louis' later years was bitterly resented; and if his proposals are no more than reactionary traditionalism they are at least striking in the whole-hearted condemnation they imply. Boulainvilliers also, himself a lesser nobleman, reveals a mind utterly out of accord with the regime under which he lives. He attacks as vicious the administrative centralization which was the whole pivot of Louis' absolutism; and with a knowledge of past French history remarkable for its time, he condemns both divine right and *raison d'état* as incompatible with the well-being of the state. Like Saint-Simon he has no better remedy than the restoration of traditional institutions—a limited monarchy, a reformed administration, an active Estates-General. But Boulainvilliers had at least grasped the essential weakness of the regime he attacked; and his power of technical criticism is a new feature in the literature of his age.

Yet it is perhaps Fénelon who shows most fully how liberal was the new temper which had emerged. The tutor of the Duke of Burgundy and Archbishop of Cambrai, he had seen the working of the system from inside, and his rejection of its principles was built upon an intimate experience. He was in no sense of the word either an innovator in reform or an originator in ideas. The power he had and the influence he exerted came from the courageous clarity of the testimony he bore to the ruin worked by Louis XIV and from his determination to try all political conduct by the touchstone of ethical principle. He wrote not merely as a Frenchman but as a citizen of Christian Europe, concerned to insist upon its general interests even above the special rights of France, nor is it insignificant that his most earnest remarks should be set in the mouth of a pagan. If he had favored the revocation and applied its cruelties in his own diocese, he learned the error of persecution and insisted that France needed not merely the recall of the Huguenots but a system built upon toleration. Ultramontane though he was, he disliked the interference of the church in political affairs, since he saw that the alliance of church and state made inevitably for ecclesiastical slavery. He denied that love of one's country can absolve a patriot from duty to mankind; and he attacked aggressive war as in all cases indefensible. Not only did he urge the restoration of French

conquests, but he saw the wrong done to Europe by the French occupation of Spain, and he wrote of Protestant and tolerant Holland as the hope of mankind. To him all power was by its nature poison; and he wrote of kings that their badness is practically inevitable. They must accordingly be the mere ministers of the law; and a constitution is essential to a well ordered state. For him political authority was the rightful possession of the nation, and there was a health-giving energy in its exercise for which no despotism, however efficient, could compensate. Despotism, indeed, always saps the strength of a people, and he predicted revolution as its necessary consequence. His remedies are not, perhaps, original. A limited monarchy flanked by a system of local and central assemblies, in which the aristocracy played the predominant part, had been recommended by others. But Fénelon saw the importance of legislation as a weapon for molding character. He realized, too, that participation in government is itself an exercise in the creation of individual personality. He demanded freedom of trade, an administration whose methods are built on a careful statistical assessment of the national resources, an adequate civil service and a purified judiciary. In his emphasis on the danger of luxury, the evil of an idle class, and the necessity of education as the base of national well-being, there is, clearly enough, something of the Platonic revolutionary. And his conception of history as set out in the *Letter to the Academy*, his insistence that institutions are more important than persons, that the habits of the nation are the pith of the record, show him as a genuine precursor. Save Bayle, no thinker of the seventeenth century was more comprehensively the instructor of the eighteenth; Saint-Pierre, Montesquieu, Rousseau all went to school to his teaching.

The boldness of Fénelon's attack upon the system of Louis XIV goes far beyond that of his contemporaries. Bayle, indeed, laid down the ultimate methodology for a deeper and more destructive analysis; but his own political proposals are, toleration apart, merely the expression of the scholar's conservatism. The Huguenot exiles, most notably Jurieu in Holland and Abbadie in England, maintained with vigor the dogma of popular sovereignty; but their opposition to the regime was rather a *cri de coeur* than a soundly reasoned philosophy, and their position as exiles detracted from the

influence of what they had to say. The first ideas of French liberalism moved upon historic and conservative lines. What was proposed was to revive the power of the aristocracy, to restore the Estates-General and the provincial assemblies, to cultivate the mediaeval polity, rather than to bring the people into the structure of government. It was not until Voltaire had made England an example to French thinkers, and bankruptcy had become the eternal partner alike of success and failure in foreign policy, that revolution was accepted as the highroad to stability.

VI. France apart, European speculation in the seventeenth century is remarkable rather for its lack of distinction than for ideas by which the current thought was profoundly moved. Spinoza in Holland and Pufendorf in Germany almost exhaust the list of those who exerted anything more than a superficial influence. The reason for this barrenness is not far to seek. The devastating influence of the Thirty Years' War made men inclined to peace at any price; and epochs in which consolidation is the outcome of fatigue are rarely capable of speculation upon ultimate principle.

About Pufendorf there is no need to say much. He was in no sense of the word an original thinker, and his importance lies rather in the temper and amplitude of his mind than in any capacity for piercing to the root of political foundations. His *De jure naturae et gentium*, first published in 1672, represents an attempt to unite the irreconcilable systems of Grotius and Hobbes. Like the former he pleads for the supremacy of reason in affairs of state; and the law of nature is for him a rational rule, inherent in the character of man and enabling him to distinguish right from wrong. Like Grotius, also, he makes the state of nature sufficiently rational and peaceful to render it difficult to know exactly why civil society was ever deemed necessary. But with Hobbes he argues that most men are the creatures of impulse and that only in the civil state is respect for reason possible to the majority. This state he traced back to a twofold contract. Subjects contract with subjects to create a political community in a particular form, and subjects then contract with those designated to rule upon their respective rights and duties. He does not agree with Hobbes that the ruler is absolute. His power may be supreme, but it is restricted always by the terms of the contract. The way in which this restriction is to operate,

however, the sovereign is always to decide; and whatever validity the theories of Hobbes possess against the arguments of the great Dutch thinker must hold against Pufendorf also. He resembles Hobbes in his low view of men, his emphasis upon the worthlessness of the multitude, the emphatic repudiation of the Grotian hypothesis of a law of nations binding upon all men because it embodies the best experience of mankind. But the really outstanding feature of Pufendorf's work is its insistent secularity of temper. He will have nothing to do with explanations of political authority which find their source in theology; and he roundly denounces the defective obscurantism of contemporary ecclesiastics who seek political philosophy elsewhere than in the behavior of men. He is, in short, comprehensively rationalist in outlook; and the immense success which attended his book is evidence of the degree to which the rationalist principle accorded with the demands of the time.

Yet for all his success it is difficult to see in Pufendorf much more than a sublime mediocrity. Spinoza of course is one of the outstanding names in the whole history of political philosophy. But it is to be remembered that for almost a century after his death his influence on politics was small. Pufendorf and Bayle seem only to be outraged by his ideas. Locke does not mention him, while Vico dismisses him in one contemptuous sentence. It was not until the time of Lessing and Goethe that his supreme merits were understood in any effective degree.

The reason, indeed, is not far to seek. For him, as for his political master Hobbes, the whole basis of politics was rigorously utilitarian; but he differed, as he himself said, from his illustrious predecessor in that he applied his method with undeviating consistency. If there are present in him things like the state of nature and the idea of contract, none of them is essential to his method. His central thesis is the identity of right with power; and he uses the experience of history—his knowledge of events is remarkable for his age—to prove that the lesson of history is a justification of liberalism. For in the long run, Spinoza argues, the true and eternal sources of power are rational in character. The action of the state is always limited in fact by the knowledge that men are always measuring themselves against it; and it has power only as they fear it or love it. But, again in the long run, it cannot control those

things which men "cannot be induced by rewards or threats" to accept; therefore opinion and religion are outside its sphere. A state, he urges, cannot make men moral or religious, and its true strength is dependent upon their morals and religion. The true springs of action are in the internal nature of men, and the power of the state gives only outward conformity, which is never permanently decisive. Force, therefore, for Spinoza is powerless without reason. The ruler's right is thus limited by his wisdom and insight, by the measure of his justice and forbearance. For otherwise his subjects will depose him, or the civil state will be a condition of anarchy tempered by despotism. Wherever, he argues, there is sedition, there also is to be found governmental wrong. Nor does Spinoza think differently of international relations. Expediency suggests here, as in the internal economy of the state, the ultimate wisdom of the golden rule.

No more striking defense of liberal principle has ever been made in purely utilitarian terms; and it is upon the same terms, also, that Spinoza bases his defense of democratic systems. Here, indeed, the deep influence of Holland upon his theorems is obvious. The necessity of checks and balances, a wide diffusion of power to safeguard local liberties, the insistence that in a democracy alone is the government most representative of the community—this could hardly have been said in the seventeenth century save by an Englishman or a Dutchman. To Spinoza monarchy is clearly abhorrent; and though he analyzes the aristocratic principle with some sympathy, it is clear that the unfinished portion of the *Tractatus politicus* was to have been the culminating point of his speculation. Even as it is, the implications of the doctrine are unmistakable. The core of the argument is the insistence that the best government is that whose policy embodies the maximum self-interest. This is democracy because it allies with itself the will and the reason of the largest number of citizens. It makes their power its own; and it thus makes its right more permanent by the identification of their well-being with its own fortunes.

The eighteenth century, therefore, inherited from its predecessor a tradition of which the liberal principle was definitely a part. The idea of consent had been everywhere adopted as the obvious answer to the divine right of kings. The notion of utility had been everywhere put forward as the test to which the monarchical

system must conform. Consent meant the consent of men; utility meant the test of results. Each was in its essence an appeal to reason against an appeal to a principle of authority clothed in some mystic sanction which reason was unable to penetrate. This liberalism, indeed, was as yet a method of examination, a challenge to the existing order, rather than a philosophy which had become a part of the normal mental climate of the generation. It needed the moral bankruptcy of church and state before liberalism could move from a thesis of reform to a thesis of revolution. The work of the next generation was to apply it to existing institutions with an incisiveness and a determination which exhausted the moral credit of the new order. When that was done, liberals were in a position to prove that they had come not less to fulfil than to destroy.

VII. Until the seventeenth century was well advanced, historical studies had for the most part assumed three forms. Sometimes, as with de Thou, they recorded the passage of events as these impressed a single observer; they are the generalization of a diary rather than the philosophic examination of a record. Sometimes, as with Rymmer, they are carefully compiled documents which are less history than the materials of history, even if, as with Tillemont, they reveal a learning and a documentary insight in advance of anything previously known. Or again, as with Bossuet, historical writing may be the anteroom of a particular theology, an exercise in the proof of a definite religious thesis, instead of a scientific effort to explain the evolution of civilized life.

It cannot be said that the seventeenth century saw any revolutionary change in the attitude to historiography. The necessity for care in controversy produced by the multiplicity of religious sects conduced to a greater precision in the handling of evidence; the great Anglican school of men like Usher and Bingham did notable work in the reconstruction of early religious history, and Tillemont, Baluze and Mabillon began forging the essential weapons of scientific scholarship. Yet even though such works as those of Bacon on Henry VII, of Selden and Conring on legal antiquities, of Gruter on classical inscriptions make it clear that a new and secular temper was emerging, the area of its activity was as yet by no means wide. Bossuet was able to suppress Père Simon's effort to handle the Old Testament in

a critical spirit. Lanoue's analysis of martyrology earned him abuse and not understanding. Pouilly's investigation, in 1722, of the legends of early Rome merely led to his denunciation as an atheist. Until the very end of the *ancien régime* it was both difficult to procure materials and dangerous to announce untoward results. Fréret went to the Bastille for denying that the Franks were Gauls. Giannone died in prison for his history of Neapolitan institutions. The Common Council of London withdrew its grant from Carte for maintaining that the Pretender had cured the "king's evil." Muratori could not gain access to many princely archives lest his researches should disturb some princely title.

Yet the progress of a rationalist temper is unmistakable. The skepticism of Bayle made possible the rationalism of Voltaire. Bentley in England, Reimarus in Germany, Vico in Italy made it evident that the critical attitude was European in its extent. When Hume in the mid-eighteenth century wrote his history of England he was attempting a broad narrative of the national life such as literature had not previously known. With many faults it added notable qualities to English historiography. If it was often prejudiced it was never enthusiastic; and the *odium theologicum* was entirely absent from its pages. Hume saw, too, the significance of social and economic history; and if he used his insight too casually, at least he used it. No British writer had previously seen the need to weave the threads of historic events into a single whole. What he began, Robertson continued. Nothing now remains of the histories of Scotland, Charles v and America with which he delighted his generation; although the man who gave to Keats his finest metaphor may perhaps rest content to have been supplanted by later research. Yet Robertson, like Hume, has great merits. He made history literature, and it did not leave his hands the servant of a particular party. He brought together a great mass of facts into an orderly and coherent whole. He was neither profound nor widely read; but at least, like Hume, he made mere analytic compilation obsolete.

Both Hume and Robertson show that it was beginning to be difficult to retain history as the servant of authority; Voltaire and Gibbon make it evident that, in truth, the battle of rationalism was in its large outlines already won. With Voltaire a new epoch in historiography genuinely begins; the critical spirit takes possession

of its kingdom. Providence is banished from the stage, passion is analyzed by the cold weapons of reason, civilization becomes the phenomenon to be examined. He realized the significance of documents. He understood that the worth of history is dependent upon the worth of testimony. If he hardly grasped the category of time, at least he understood the category of space. With him Christianity is no longer the central theme but simply an incident in universal history. His books are no longer either pamphlets or funeral orations but genuine attempts to explain the phenomena he encountered. He speaks like an analyst and not, like Bossuet, as a prophet. He banished the supernatural from history and thereby brought it down from the clouds to earth. If the *Essai sur les mœurs* is today inadequate, it is only because he pointed out the path by which its inadequacy might be made known. If we do not accept his view of Louis XIV as he conceived it, it is still in large outline his method of interpretation that prevails. Voltaire wrote history as a humanist, and he had the insight, accordingly, to see that nothing human was unworthy of his examination. The people as well as the court, the lawyer as well as the soldier, the man of letters not less than the priest—these enter for the first time into the necessary ambit of his scheme. A critical philosophy of history would doubtless have come without Voltaire; but no man made its coming more certain or its success more assured.

If the ambit of Gibbon was in a sense less wide, the character of his achievement was hardly less notable. The *Decline and Fall* is one of those books literally beyond praise; and it may be said with confidence that no work of its amplitude has ever been less touched by the corrosive hand of time. Here let us note that, proceeding though it did from a political reactionary, it is yet a manifesto of liberal rationalism. The famous epigram, "I have described the triumph of barbarism and religion," connotes not merely a history written in cold antagonism to religious belief but the first genuine attempt to describe Christianity as a sociological phenomenon; and if we should perhaps be kinder than Gibbon to the theologians and ecclesiastics upon whom he heaped contumely, no scholar will be found to dissent from his annihilating confutation of his religious critics. This rationalist philosophy of history, moreover, is accompanied by a sense of the continuity of history that was epoch making. No one had

seen before Gibbon that the Augustan empire fell only with the fall of Constantinople. Criticism has overthrown his attack on Byzantium; it has shown that, as in his chapters on Mohammedanism, he sometimes used untrustworthy sources. The answer to all such attacks is that he wrote before the nineteenth century, and that he made a large part of the achievement in method and outlook of the nineteenth century possible. He rescued a vital field of research from those who had made it the plaything of theological passion. He gave to that field both a new definition and a new perspective. With Voltaire he gave to the secular interpretation of history the letters of credit which assured to it its future empire.

VIII. For Catholic and Lutheran Europe the Reformation meant an autocratic and centralized state; and if the special experience of England and Holland required there different political institutions, nevertheless the economic ideology of Europe is, after the Reformation, different only in the varying degrees of its intensity. The decomposition of the mediaeval system, the rise of manufactures, the development of commerce, the new possibilities opened up by geographical discovery and the use of the mariners' compass, the growth of banking—all these meant, in their total and complex impact, the rise of national economic systems. It was inevitable that the state should seek to control this evolution. An increase of national wealth not only meant an increase of national power; it afforded a basis for taxation which fostered the political ends the state sought to serve. The history of economic policy before Adam Smith is thus very largely the history of a deliberate effort by the state to foster economic development. Burleigh's encouragement of maritime power in England, the relation, in Amsterdam, of the bank to the city council, the ordinance of Louis XIII permitting wholesale merchants to attain a patent of nobility—all these show clearly that the importance of the new industrial phenomena was clearly apparent to the mind of the government. The colonizing activities, the economic policies of Cromwell and Colbert, simply illustrate the same method in more intense form. The governments of the *ancien régime* became the patrons of capitalism as a means of promoting their own authority.

The conditions created by the Reformation inevitably sharpened this atmosphere. Catholic supremacy had meant the imposition of a social

and moral discipline which made ethical assumptions constantly conflict with everyday behavior. The true Christian life, in that view, was the life of the monk; and accumulation of wealth was hardly regarded as a praiseworthy ideal. Asceticism of this kind was obviously unfavorable to individual initiative. It left the average man in the grip of a dual view of the universe which contrasted worldly advantage with the religious ideal. Luther destroyed the dualism by making the internal voice of conscience the criterion of external conduct; as Sebastian Franck said, the monastic ideal became with him a world ideal. That was already an aid, since the voice of conscience is conveniently various in the precepts it adumbrates. It was Calvin more than any other thinker who provided the new capitalism with the ethic of which it had need. His view of man as the guardian of what God has given to him and his insistence upon occupation as a "calling," fulfilment of which is service to God, enabled the view to be justifiably taken that accumulation of wealth is a religious exercise, and that association with the business man in that task—the gospel of hard work and low pay—is an avenue of salvation. Calvinism, in a word, provided a way of transition from a society in which economic life was dominated by religious conceptions to one in which, with the growth of secular power, religious conceptions should be expelled from economic life. Not, indeed, until the threshold of the early nineteenth century was the evolution at all fully accomplished. But the basis of its coming is clearly present, once economic growth was made the basis upon which the national state was to wax strong.

Mercantilism is essentially the system which expresses, in its first large phase, the result of the decay in religious discipline which the Reformation marks. It is impossible to define it in a phrase. Rather it expresses a series of tendencies which in any given country exist in varying degrees of emphasis. The mercantilists were never a school, and they did not completely agree with themselves nor teach a consistent body of doctrine. In general it may be said that they were the proponents of four large principles. They insisted on the value of possessing a large supply of the precious metals. They preached the superiority of foreign trade over domestic and, as an almost necessary inference, of industries which manufacture from, over industries which supply, raw materials. They argued, finally, that the state

can by its deliberate policy artificially promote these desirable ends. Nor is it difficult to see why these views should have seemed desirable. To a generation which had seen the advent of a money economy, the virtual identification of wealth with bullion was natural enough. To one, further, which saw the rise of great centralized monarchies and an immense growth in the number of officials, a sense of the power of the state was inevitable. To the state itself industry seemed a natural field to foster, and the prohibition of imports a wise policy to pursue, since each led to an increase of revenue and thus an increase of the striking power of the nation. So, also, to use colonies as the reservoir of exports, to prohibit even them, so far as possible, from manufacture, was to strengthen national economic power. Mercantilism, so regarded, was a natural expression of the actual policy of the time. Traders urged it upon governments to protect themselves from foreign competition; and governments accepted it as the obvious path to the enhancement of their authority.

Mercantilist doctrine is, in fact, characteristic of any period in which liberal theories are at a discount. For liberalism tends to a cosmopolitan outlook, and the day for that standpoint had not yet come. The doctrinal expositions we have are essentially practical treatises intended for a particular state, and considering mainly some special and immediate national advantage. Thus the currency revolution effected by the discovery of the American silver mines led to a spate of treatises on money, some of them, like the *Réponse au M. Malestroit* of Bodin, very partially mercantilist in outlook. But in the *République* Bodin expresses the typical views of the system. He is strongly in favor of state intervention in industry, and eager for high duties on foreign imports. In England, almost simultaneously, the author of the *Briefve Concepte of English Policy* went further and actually proposed not merely the exclusion of all foreign goods capable of being made at home, but also a prohibition upon the export of raw materials abroad. Within thirty years Antonio Serra was striving, in his *Breve trattato*, to use the prosperity of Venice and the poverty of Naples as proof that the industrial state on mercantilist principle is definitely superior to the agricultural state.

The volume of this literature in the seventeenth century is enormous. In France Montchrétien has secured an enviable reputation for

his *Traité de l'économie politique* (1615) in which the name of the science appears for the first time; but the book is in fact a mass of wholesale and unacknowledged plagiarisms from Bodin and his own contemporary Laffemas. The need for colonies, the importance of government control, the danger of economic individualism, are all emphasized with enthusiasm. Thomas Mun in England did a similar work. Laying down with passion the thesis that the business of the state is so to arrange the balance of trade as to attract money from abroad, he indicated a host of expedients to this end. Mun is merely typical of a number of writers, like Misselden and Pollexfen, who urged the same views.

By the middle of the century, however, there are signs that faith in mercantilism is beginning to waver. The remark of Colbert that protection is a crutch with which the sound limb dispenses is well known. While Sir Josiah Child was a mercantilist upon colonies and the rate of interest, he did not object to the export of bullion, supported the Navigation Acts upon political rather than economic grounds, and saw that an import trade is the unavoidable result of foreign commerce. Charles Davenant, at the end of the century, while mercantilist upon colonial policy, went much further toward liberal ideas in other directions; and Sir William Petty, in this, as in much else, a mind of profound originality, laid down a body of doctrine which links him directly with Hume and Adam Smith. Indeed it may be said that by the end of the seventeenth century England possessed in Barbon, Dudley North and the anonymous author of the remarkable *Considerations on the East India Trade* (1701) an economic outlook which denied at their root all the fundamental mercantilist notions.

France, moreover, was tending in the same direction. The disastrous policy of Louis XIV resulted in a general economic impoverishment, and even in an age when criticism was dangerous, protest against mercantilism began to make itself heard. Boisguillebert was the ablest of the dissidents from the traditional form of mercantilism. In his emphasis on the importance of agriculture he combined what may be called an agrarian mercantilism with elements of a newer doctrine. While he believed in high import duties for the products of industry, he was specially concerned with the problem of improving the position of the agriculturist. He approved not only import duties on wheat but

also export bounties. He was freely cited by the physiocrats because of his insistence upon the primary importance of agriculture. But in fact his approach to the problems of economic policy was quite different from that of the physiocrats. Vauban's analysis, however, was built rather on social sympathy than upon economic insight. But he too has a profound sense that the mass of governmental regulation inhibits rather than promotes prosperity, and his proposed scheme of taxation would have wrought a revolution in the economic policy of the state. The fact, moreover, that a moral philosopher like Fénelon can urge the necessity of freedom of trade shows clearly that liberal ideas were gaining ground.

The reason is not far to seek. Industrial policy in the preceding age had been made subordinate to military policy; or, as with the suppression of the Edict of Nantes, to considerations which totally disregarded secular well-being. The zest for adventure was unsuccessful, and the economic theorists began, like those in matters of religion and politics, to look to freedom from governmental interference as the key to social good. Exactly, in other words, as experience of the state or church as an organ of repression led Voltaire and Diderot, Montesquieu and Holbach to look to religious toleration and political liberty as the ideal, so did the mistakes of the state as the arbiter of commercial destiny lead to an emphasis upon the desirability of *laissez-faire*. The movement did not come all at once. After Vauban and Boisguillebert there is a period of stagnation which lasted for almost thirty years; for men like Dutot and Melon were still set by the ancient ways, and Montesquieu, although an advocate of economic liberty, nowhere attempted systematic exposition in the economic field. It was not until the rise of the physiocratic school that a liberal policy was developed as a complete philosophy of economic life.

The originator of the physiocratic doctrine was Quesnay, the physician of the Pompadour; but the school of thought he may be said to have founded had wide ramifications. The elder Mirabeau, Mercier de la Rivière, Dupont de Nemours and Baudeau are only the most notable of the direct disciples; but Turgot and Condorcet were deeply influenced by them. Their power over public opinion was never great, and it may be said to have ended when Adam Smith embraced the most valuable part of their teaching in an outlook wider than theirs. But they were the first group of thinkers system-

atically to study economic problems in terms of liberal principles. They had, as Dupont said, "a body of doctrine defined and complete, which clearly lays down the natural rights of man, the natural order of society, and the natural laws most advantageous to men united in a society." Their starting point was the belief that there are natural laws underlying the social world as final and as real as the laws which explain the physical universe. These laws men must obey in order to secure the advantages of social organization. With their special economic doctrines, as with their insistence upon the value of benevolent despotism, we cannot here deal. What is important is their insistence that maximal production is the effect of the greatest possible liberty to trade. They object, accordingly, to all restrictions upon labor; and their defense of the individual's right to acquire property is, at bottom, an argument that interference with individual effort is an injury to national prosperity because in hindering ownership it removes the basic stimulus to production. Their view of society as essentially an aggregate of individuals, each of whom is not merely pursuing his own self-interest but is also the best judge of that self-interest, naturally led them to regard government as a necessary evil, whose interference should be limited to protecting the rights of one from invasion by another. The ideal government thus becomes that which has least concern with its citizens. Enlightened self-interest, in their view, was much more likely to result in social good than the system of minute regulation and hampering restriction. Obviously this outlook represents the deep distrust of men who had known mercantilism by grim experience. Their view of society was built upon the political and psychological considerations which made Locke the messenger of liberation to the eighteenth century. Their attitude to nature showed the impact upon them of the scientific revolution. For them reason can discover the laws of the social world, and no government can disregard the relentless operation of these laws.

They came in their due hour; though Germany still remained, with rare exceptions as at Baden, tied fast to the ancient ways. For in Germany economic theory was essentially a by-product of public administration and not an independent criticism of state policy. It arose out of the teaching of economics to men who were to devote their lives to some form of administrative effort. The cameralist tradition,

as it is called, was thus inevitably an effort to clarify, and not to criticize, the work of government. The professors of economics were themselves civil servants, holding chairs founded to enable them to offer practical instruction. The result is a body of ideas intended especially to explain how administration can be best conducted to the best advantage. Such men could hardly be expected to belittle the sphere of the state; they were concerned with practical questions of tariffs, taxation, forestry, mining. Mercantilism naturally expressed the categories of thought they required; and all the leading German cameralists of the seventeenth century accepted, like Bornitz and Schröder, the traditional doctrine. Nor does the eighteenth century see much change. Justi and Justus Möser were unaffected by the new ideas; and though Zincke and Sonnenfels show gleams of a fitful temper, their order of thought was hardly in advance of that of Davenant or Melon. The dominant school was made by the physiocrats and their allies. They showed that the individualism which the Reformation portended had at least extended its empire to the economic sphere. Hutcheson and Hume, the physiocrats and Adam Smith, when they propounded the system of natural liberty, were only completing the triumph of that critical rationalism which was born of the revolutionary experience of the sixteenth century.

For it may be said without exaggeration that after the eighteenth century the policy of the

state is above all distinguished by the subordination of its power to industrial need. The recognition is consequent that the commercial life of the nation is the supreme manifestation of its activity. The central theme of political policy thus became the supply of what commercial life required for its full expansion; and to this all effort in the community was increasingly subordinate. The religious discipline to which the individual had been formerly subject could then be replaced by an ethic derived predominantly from economic circumstance. The source of social regulation was no longer supernatural authority but rational utility. The system of natural liberty, moreover, was discovered to result in a harmony of interest between all members of society. This gave to liberalism the character of a doctrine entitled to optimism because, since the individual was thus simply able to realize himself most fully, no limits need be set to the bounds of progress. Laissez-faire as a program was the logical counterpart in social philosophy of Protestantism in the religious, of free inquiry in the intellectual, sphere. Each came as a herald of freedom to an age hampered by obsolete principle. Each definitely enlarged by its victory the area in which the human spirit was free to voyage in self-discovery. But each in its adventure was to find that the abolition of unnecessary social restraint was not identical with the creation of necessary social control.

HAROLD J. LASKI

VIII

The Revolutions

I. It is perhaps a fallacy to consider the revolutions of the latter half of the eighteenth century, the American, the French and the industrial, as manifestations of a common revolutionary spirit working to lay the foundations of modern society. Certainly the changes brought about in these years were complex enough, and sufficiently dependent on earlier changes, to make the historian cautious. Moreover the example of the eighteenth century writers themselves must serve as a warning against too inclusive generalizations. Yet there does seem to be in the western world at this time a very definite *Zeitgeist*, a common attitude distinguishable both in thought and in action. Saint-Just gave this attitude profounder expression than he doubtless knew when he told the Convention, "le bonheur est une idée neuve en Europe." Happiness for everyone was attainable, not in some distant heaven, but here and now on this earth. If old habits, old beliefs, old institutions stood in the way of this happiness for the common man they must be altered. One cannot look into the files of an eighteenth century magazine, or study the life of an eighteenth century man, without becoming aware of this acceptance of innovation. Experiment, in fact as in idea so foreign to the Middle Ages, had by the eighteenth century become a commonplace.

This change appears most obviously in what we may call the revolution in things. It was prepared by the remarkable progress of the physical sciences. Newtonian physics were brought by Voltaire to the level of the *salon*, and very ordinary men came to see the material universe ruled not by mysterious divine laws but by discoverable natural laws. These laws were, it is true, immutable; but once discovered, man had but to adapt himself to them to find himself perfectly at ease with his environment. Moreover was it not obvious that man, too, was a part of the material universe? Much of eighteenth century work in the social sciences is an endeavor to find for human society laws of nature, not in the sense Grotius gave the phrase, but in the sense Newton gave it. Both physics and chemistry progressed throughout

the century by the work of careful investigators, and toward the close of the century Lavoisier gave to chemistry its modern form. The biological sciences did not attain the same completeness; but even here the work of so typical a man as Buffon is very important. For Buffon, although he was hardly a biologist in the modern sense, did help enormously to popularize the study of "natural history"; and from that study there emerged a clearly evolutionary concept of organic life, and a geology which Buffon himself had difficulty in reconciling with the book of *Genesis*. Academies and the learned societies increased their scientific activities, and all sorts of men busied themselves with scientific experimentation, and sometimes made valuable discoveries. Franklin, of course, comes to mind at once.

Franklin was not only a scientist but an inventor. His work is an example of the utilitarian purposes to which these studies were turned. Invention was a necessary element in the industrial revolution, and the work of Arkwright, Watt, Cartwright and other English inventors helped to determine the rise of manufacturing in England. Yet this familiar role of invention in the English industrial revolution is of less importance in the study of eighteenth century thought in the social sciences than is often assumed. The middle class in France and in England did indeed furnish most of the writers on social questions, and determined the nature of their thought; but this middle class had been enriched not by the industrial revolution, which had just begun, but by the earlier development of commerce. The literature of protest against the conditions brought about by the industrial revolution grew up much later, and began rather in France, where the industrial revolution was late, than in England, which was very early industrialized. The real importance of mechanical inventions in a study of the social sciences in the eighteenth century lies rather in their psychological than in their industrial effects.

For these inventions, applied to a host of domestic purposes, helped to give to the average

man something of the modern attitude that nature exists to be conquered. In 1783 the brothers Montgolfier sent their first balloon aloft, and two years later Pilâtre de Rozier achieved a very modern death attempting to cross the English channel in the air. In less spectacular ways land travel was speeded up enormously through improvement in road making, in coach building and in the organization of posts. Agricultural methods were improved, and household conveniences increased. In fact the eighteenth century was quite sure that it had already attained a state far ahead of previous ages. The carping conservative existed, of course, as he always has, but the feeling was quite general that man is a creature of great possibilities and that there is no limit to his ability to improve the conditions of human life on this planet. The idea of progress, discernible clearly enough in seventeenth century writers like Descartes and Bossuet, is fully developed in a host of eighteenth century writers such as Turgot, Rousseau, Condorcet and Adam Smith. The idea is even given a biological application in Lamarck's theory of evolution, where the will does wonders with environment. Need it be pointed out how far this perfectible man is from the fallen man of Christian tradition?

From improvement in material environment it is an easy step to improvement in political and social environment. The revolution in institutions was no less marked than the revolution in things. The characteristic form of this revolution up to the very end of our period, however, was not popular but autocratic. Most of the writers with whom we are concerned lived under a benevolent despotism. Frederick the Great, Catherine and Joseph II are stock examples, but George III and Louis XVI, each in his own way, were trying hard to be benevolent despots. Voltaire, for all his humanitarian enthusiasms, could hardly conceive any effective agency for reform other than a wise ruler. Modern knowledge made possible great improvements in the condition of the people, but the people themselves were too ignorant or too selfish to take the philosophic view, and reforms must be made from above. The king was no longer to rule by divine, but by philosophic, right.

Benevolent despotism, however, could not long contain the reforming spirit of the age. Too much, for one thing, depended on the personality of the despot, and the supply of

despots was irregular. Moreover in France and in England the well-intentioned efforts of the crown met from the start with an organized opposition supported by what may be called the popular party. Reforms were usually made piecemeal, and often disturbed established interests without pleasing those supposed to benefit from the reforms. The career of Turgot in France shows how uncertain a reforming monarchy could be. Finally these reforms were essentially paternalistic, and gave insufficient outlet for the energies of the rising middle class.

That class was now in most of western Europe thoroughly prepared to fend for itself. For generations it had been growing richer. Less tempted than the nobles to spend money on mere luxuries and often indeed forced into plain living by Calvinist or Jansenist principles, the middle class had profited by the expansion of trade to secure a position of economic power more advantageous in many ways than that of the old landed nobility. And following what seems to be a law of politics, it was seeking to gain a political power corresponding to its economic power. With increasing wealth came also increasing opportunities for education. Pedagogy itself, in spite of Rousseau and Pestalozzi, made little progress in the eighteenth century. Most middle class boys received a thorough classical training, which later bore fruit in a host of revolutionary Brutuses and Mucius Scaevolus. What was really important, however, was the opportunity for a continuous adult education afforded by the great increase in newspapers, periodicals, lending libraries and reading clubs. Much of the literature of the time, from Defoe, the English essayists and their French and German imitators on to the encyclopaedists, is written for the middle classes and, if the Marxian implications of the phrase can be forgiven, is definitely class conscious. In a hundred plays and novels the besotted and vicious nobleman is outwitted by the virtuous commoner.

In the American and French Revolutions the middle class achieved political power. In England the revolution began with Wilkes and Middlesex, though it did not translate itself into institutions until 1832; yet the slowness of the change ought not to blind us to its reality. England, like the rest of the western world, underwent a political revolution in the eighteenth century. Fashions in historical writing have occasionally obscured the fact that the American Revolution was a social revolution as

well as a civil war. Certainly, however conservative a Hancock or a Washington may have been, the repercussion of the American Revolution in Europe had anything but conservative results. The French Revolution, however, remains the pattern of the modern democratic movement, and the focus of the ideas with which the middle class began its rule. A republican form of government, universal suffrage, equality before the law, universal education, abolition of government and other monopolies in trade, and the career open to talents—these, if not actually realized, were all a part of the program of the first French Republic. "Liberty, Equality, Fraternity," became a symbol in which the more idealistic aspirations of the people could be centered; patriotism became a fact which satisfied their more practical aspirations. Modern democracy had found its institutions.

The revolution in ideas is no less real than the revolution in things and the revolution in institutions. The textbooks have labeled this movement the rise of romanticism. Now there is no great objection to assigning to the word romanticism ethical and philosophical implications which cover the whole field of human thought, although clearer thinking might have resulted from limiting the word to aesthetics. But granted that romanticism is an attitude toward life, it was surely not the attitude of all the revolutionists. What was really new in late eighteenth century thought was an extraordinary blend of rationalism and romanticism. Rationalism employed the methods of logic, refined and improved by generations of thinkers, to demonstrate the weaknesses of existing institutions, and to construct in theory institutions without weaknesses. Romanticism brought to these theories a faith and an animal energy without which they could hardly have moved men to action. Romanticism in the age of revolutions was thus the complement of rationalism. The calculating Bentham and the mystic Wordsworth are both revolutionists; and sometimes, as with Rousseau, who wrote not only the *Nouvelle Héloïse* but also the *Contrat social*, the same man is both romanticist and rationalist. The two attitudes were soon to part company in the history of thought; romanticism, finding more emotional satisfaction in ancient irregularity than in modern uniformity, was on the whole to turn conservative, while rationalism, newly christened utilitarianism, was to continue on the side of the innovators. But the point for us to

notice is that in the latter half of the eighteenth century the rationalist temper, seeking to translate into life the orderliness of the thought process, and the romantic temper, seeking an ecstasy beyond thought and sometimes beyond life, did collaborate in the attack on the *ancien régime*.

In such a historical setting it is not surprising that what we now call the social sciences should have attracted active minds. There seem to be good reasons for believing that in the latter part of the eighteenth century more intellectual energy was spent on the problems of man in society, in proportion to other possible concerns of the human mind, than at any other time in history. Such a statement is perhaps an exaggeration, and certainly is not susceptible of proof; but it ought to focus attention on the extraordinary place occupied by the social sciences in the life of the time. Hardly anyone seems free from sociological preoccupations. French literature is almost too perfect an example. It is hardly possible to find among French writers between 1750 and the revolution one who, like Villon, like Ronsard, like Racine, has wholly an artist's interest in his fellow men. Any literary form could be adapted to the purposes of the reformers. The public found political allusions in Voltaire's very classic dramas; moralists took over the novel, cleansed it of its picaresque impurities, and used it to persuade men to social virtue; and lyric poetry, which seemed of little use to the sociologist, was abandoned. The difference between pure literature and literature inspired by social purpose will be very clear from the slightest comparison of a work like Longus' *Daphnis and Chloë*, which is a real idyl, and Bernardin de Saint-Pierre's *Paul et Virginie*, which is propaganda in favor of the state of nature. But English literature is hardly behind the French in its preoccupation with the problems of man in society. Gray is almost alone in his elegiac indifference to so light and necessary an evil as politics. You may extract bits of Rousseau from *Tom Jones*; and as the century goes on, lesser novelists like Bage, Holcroft and Mrs. Inchbald are nothing but propagandists; Johnson was a moralist and a Tory, and certainly wrote no pure literature. In Germany literature from Gleim and Gellert to the young Schiller, though its main concern may be to nourish intensity of feeling, is certainly more moralistic in tone than lyrical.

The point we have made as to literature, that

it kept branching out into the social sciences, could be made in the same way about other fields of human activity. A few names will have to suffice: Frederick the Great, chiefly a king, but also a *philosophe* and author of an *Anti-Machiavel*; Turgot, civil servant and economist; Mirabeau, great lord and economist; d'Alembert, mathematician and moralist; Tucker and Price, clergymen both, the first an economist, the second a political philosopher; Priestley, chemist and political philosopher; Franklin, merchant, scientist, inventor and philosopher; Burke, at once a politician and a great political thinker—perhaps the most surprising combination of all. So far indeed did this invasion of other fields of thought by the social sciences go in France that the word *philosophe*—a word on everyone's lips at the time—though it can hardly be translated into modern French, is probably most nearly rendered *sociologue*.

Whether this extraordinary flowering of the social sciences came about through the revolutionary tendencies of the age, or whether these revolutionary tendencies came about through the flowering of the social sciences, are questions that can be finally answered by faith alone. But it may be pointed out that both the advancement of the physical sciences and the rise of the middle class determined, if not the existence of the social sciences, at least their character and development. The human intellect had mastered astronomy, physics and chemistry by discovering the uniformities or laws behind the apparent diversities of nature. What more natural than to attempt by the same means to discover the laws of politics or economics? Then, with the growth of the middle class in wealth and in education, there came an inevitable increase in interest in man as a social and political animal. For the middle class was too large to gain its experience of politics directly by personal contact, by struggle and intrigue. It was obliged to learn indirectly from books. Moreover it could not act as a body from direct knowledge, nor could it cohere, as could any oligarchy, through the intimate relations between its members. The middle class had to learn its politics from the printed page and the lecture platform; and its politics, in order to be workable, had to be translated into theories, symbols, a ritual. Finally, since fashion is hardly less influential in intellectual than in other human activities, once men of reputation got to writing on social and political

matters others took it up. The French *salon* proved peculiarly adaptable to serious discussions about the natural goodness of man, the corrupting influence of bad governments, the relative virtues of monarchy, aristocracy and democracy and similar topics. There is no doubt that the social sciences were enjoying a boom.

Three general remarks may be made about the vast body of writings resulting from this interest in the social sciences: it is predominantly French; it is almost always politically partisan; it is comparatively undifferentiated as between separate branches of the study of man in society.

Great Britain contributed much to all the social sciences in the period, and economics is not too unjustly called in origin a British science. Yet France possessed in the eighteenth century a reputation as the center of thought and fashion which she has since lost, but which no single nation has acquired. Even English thought was spread largely through the western world in French translation or in French adaptation. The social sciences were cosmopolitan enough both in the origins and in the outlook of the men who studied them; but that cosmopolitanism has a tinge as definitely French as the manners and the clothes of the time.

Much of the political writing of the period is frankly polemical, even when it appeals to general principles, as with Voltaire; but even where the writer protests his dependence on the law of nature or on scientific principles, political purpose comes out clearly enough. A Hume may indeed maintain a skepticism about the customary explanations of the origins and continuance of civil society; but his philosophical skepticism only leaves him the freer to insinuate conservative preferences in practical matters. Most of the writers of the time, however, are definitely on the side of innovation. The *philosophes* in France were accused by their enemies of being a sect, and at the very least they were a political party of advanced views. English economics was revolutionary enough in its attitude to certain established institutions. In fact Burke is almost the only genuine conservative among the great political thinkers of the period.

What is most surprising to the student of today in eighteenth century social science is its lack of differentiation into fields—political theory, jurisprudence, sociology, social psychology, anthropology and so on. This may appear at first to denote a surprising versatility

in individual writers. Condillac is a psychologist and also an economist; Adam Smith is an economist and holds a chair in moral philosophy; Montesquieu is jurist, historian and sociologist; Rousseau an educational psychologist, a political theorist, even a bit of a theologian. But the difficulty goes beyond individual versatility to the works themselves. Just how is *De l'esprit des lois* to be classified? or *Dei delitti e delle pene* (which is obviously too humanitarian to be strict jurisprudence) or Raynal's *Histoire des Indes* (which is hardly history at all)? The fact is simply that specialization in the social sciences had not yet set in, and that we shall have to bear this in mind in judging what the late eighteenth century contributed in this field. And for the purposes of a brief review of the leading writers we shall have to employ a very simple classification: first, political writers, a necessary catch-all term to cover the very undifferentiated nature of the field; second, economists, a fairly definite group of men; third, historians, who again are pretty well earmarked as such.

Montesquieu's *Esprit des lois* (1748) is the natural point of departure for a study of the political writers of the age of revolutions. It quickly attained enormous prestige, it obviously had an influence on political action, especially through its emphasis on the doctrine of the separation of powers, and it remains today a political classic. What seems to us now its chief virtue is its attempt to explain existing laws in terms of the whole of human life. Montesquieu finds in any given state a set of laws; these laws have, he believes, been brought into being by the complex play of natural causes—the size of the country, its climate, the religious beliefs of the people, their wealth, their commerce, their morals, their political constitution. By a careful study, then, of these observable facts in the social life of a people he hopes to be able to show how their laws are adapted to their character and circumstances. Once he has succeeded in showing how this adaptation came about, he is in a position to suggest ways of making it more perfect, of providing for a given people a better set of laws. But he will not make the mistake of spinning out of his own brain an ideally perfect set of laws, suited to all times and to all places. By going to facts instead of to philosophy, he has become convinced that all legal systems are relative to particular, and varying, conditions of life. Although there is implicit in it a kind of

historical fatalism, the *Esprit des lois* none the less approaches the study of law from the point of view of the sociologist, the psychologist and the historian; its method is essentially inductive. In these ways it is still a very modern book.

But Montesquieu had the greatest success with his contemporaries at precisely the points where he seems false to his method. No scientist of course believes that facts take care of themselves, even in induction. But in true induction hypotheses seem to grow out of a collaboration between observed facts and the mind of the observer. Montesquieu's famous classification of governments, which fills the first eight books of his work, shows evidence of a desire to fit facts into categories arrived at *a priori*, often for purposes of propaganda. There are three forms of government, republican, monarchical and despotic, which have respectively as principles virtue, honor and fear. Now this is inferior, both as to observation and as to logic, to Aristotle's famous classification. Moreover a despotism is merely a kind, even though a bad kind, of monarchy; Montesquieu is here clearly inspired by a partisan zeal to show Frenchmen the horrors of despotism and to prevent the French monarchy from turning despotic. He is, in short, being politically partisan. The well-known analysis of the English constitution, the principle of the balance of the three powers, executive, legislative and judicial, and the virtues of a mixed government, where king, nobles and people also contrive to effect a balance of power, is another example of Montesquieu's failure to avoid stiff, absolute, *a priori* categories. This part of his work came to reinforce Locke, and the two together have been tremendously influential; yet the modern social scientist will see in this rather an attempt to mold facts to a theory than a true induction. That the theory, in spite of its incompleteness, should have proved fruitful both in practical politics and in political thought need not surprise us. The eighteenth century had a way of jumping at conclusions and then acting upon them. But the importance thus given to the conclusions forced critics to a renewed and more careful study of the problem. The history of the doctrine of the separation of powers in the United States is a case in point.

The political thought of Voltaire is scattered throughout his vast work, in his histories, his *Dictionnaire philosophique*, his satires and his correspondence. He never wrote a systematic

treatise on government, and it is idle to seek to found an orderly system upon his "chaos d'idées claires." But his influence at the time was so great that the historian of opinion cannot neglect him. He is the great theorist of the benevolent despots. He has no faith in the common man, and is neither emotionally nor intellectually affiliated with the democratic movement. Yet he did in practise become its ally and, after his death, one of its patrons. Voltaire helped the democratic cause and incidentally the growth of the social sciences, first, by his steady opposition to intolerance and bigotry, second, by his willingness to criticize any established institution in the light of reason, and finally, by his admiration for the liberal elements in the English constitution. He is particularly important as one of the chief sources of inspiration for the anticlerical movement which has since played such an important role in European politics.

Rousseau is the third of the triumvirate upon which writers have often thrust responsibility for the French Revolution. The *Contrat social* (1764), though it no doubt served as a handbook for revolutionists, is as much a permanent addition to political thought as the *Esprit des lois*. The common criticism that men never did at any moment in history get together and sign a social contract is of course absurd. Rousseau never thought they did. The *Contrat social* is an unusually penetrating attempt to answer a fundamental question in political psychology: Why do men accept the authority of society? Rousseau employs what is after all only a figurative expression—the contract—to explain that in the long run men do what a given society wants them to do because by an act of faith they have identified their individual wills with the will of the society. Rousseau probably did think of this general will of society in metaphysical terms, as partaking of the reality which the Platonist assigns to universals. But the empiricist may well accept much of his analysis. For whether the group, and hence the group-will (general will), be real or not, the individual in his relationship to the laws and to the rulers of a group does almost always personify, or even deify, the group, and hence puts his obedience, even though unconsciously, on a religious basis. A man will accept willingly the constraints set upon him by society because he feels these constraints are set by a superior and a better will which is yet somehow the expression of something within him. At bottom

the psychology of obedience to civil authority is the same as the psychology of obedience to religious authority.

The revolutionists, of course, found much more than this in the work of Rousseau. The general will came, at least in popular opinion, to be identified with the will of the majority, a confusion against which Rousseau himself had carefully guarded. Much of the phraseology of the *Contrat social*, like the famous sentence "L'homme est né libre, et partout il est dans les fers," lent itself to the uses of political radicalism. A great deal of what Rousseau had taken pains to show could apply only to the small city-states of antiquity and to their direct democracy was given a modern application. The most revolutionary of Rousseau's doctrines, however, that of the natural goodness of man, is not to be found in the *Contrat social* but in the *Discours sur l'origine de l'inégalité parmi les hommes* (1753), the *Nouvelle Héloïse* (1760) and the *Emile* (1762). Man, regarded simply as a creature of animal appetites and passions, is essentially good. If these appetites and passions now waste themselves in corruption, it is because civilization, with its laws, its institutions, its religions, its arts and sciences, has turned them into evil ways. Even the much praised master faculty of man, his reason, has aided in leading him astray. His heart is his one true guide. Rousseau, though he did not originate this doctrine, is clearly in the eighteenth century the center from which it spread. It became in the hands of some of his successors a thoroughgoing denial of the value of thought and an exaltation of the value of feeling, and as such is the leading theme of the romantic movement. Its political consequences are clear and important. In its mildest form it is merely a belief in the rightness of the plain people, and hence in the ordinary machinery of democracy; for the common people are less corrupted by manners, education and luxury, and hence are nearer nature. In its extreme form it amounts to anarchy. For if men's instincts, pure and uninfluenced by civilized corruption, are good, then we must trust each man to follow his own instincts, and not corset him with unnecessary and vicious laws. Moreover the doctrine of natural goodness brought support to egalitarianism. Goodness is in the natural man a matter of feeling; but men obviously differ less, even in the light of nature, in their capacity for feeling than in their physical and intellectual capacities. Equality in this sense seems almost a fact.

Rousseau's doctrine of the natural goodness of man led him toward individualism; his doctrine of the social contract, whereby the individual submerges his will in the general will, led him toward collectivism. He never seems quite able to choose definitely between these alternatives. In the same chapter of the *Contrat social* (bk. ii, ch. iv) he says that the social pact gives the body politic absolute power over all its members, but that individuals possess natural rights which they must enjoy as men; that though each citizen under the pact alienates all his powers, goods and liberty to the community, he alienates only the part of these which concerns the community; that, however, the sovereign is the sole judge as to what concerns the community. He probably leans somewhat to collectivism. Both collectivists and individualists appealed to his work for support, but on the whole his practical influence has been in favor of collectivism (the Jacobins, early socialism).

Most of the men commonly grouped together as the *encyclopédistes* wrote a great deal on social problems, although the great encyclopaedia itself does not devote much space to the social sciences. Although these men gave personal interpretations of their own to many questions, they none the less stood together on important issues, and it will not be unfair to select one of them for special treatment. Holbach's *Système social* (1773) is a work obviously inferior to those we have hitherto considered. It is full of bad rhetoric and special pleading and raises far more problems than it attempts to solve; or rather it solves them with a phrase, "let reason rule." Holbach starts with a definitely utilitarian psychology. Man is neither bad nor good; he is born with an instinct to seek pleasure and avoid pain. If he is allowed to follow these instincts, that is, to pursue enlightened self-interest, he will so act that his own pleasures, and therefore those of his fellow men, are maximized. The science of politics is simply the application in society of this simple moral principle.

Society is based on a social pact, actual or assumed. Holbach is not quite sure as to who are the parties to this contract. At first it is a contract between individuals to make a society; then it becomes a contract between the individuals governed and the government, or sovereign, set up by the previous contract. But in both cases Holbach retains the Lockian idea that the individual promises obedience,

and society or the government promises protection of property and liberty, and that where this protection fails the contract is broken and the individual absolved from obedience. In the state so set up the form of government does not matter, and the old dispute as to the respective virtues of monarchy, aristocracy and democracy is an idle one. In the past they have all three proved bad, anyway. What does matter is that the civil laws of these states should correspond to natural laws, and that men should obey not other men but the law. This law of nature, about which there has been so much vain dispute, is very simple; it is simply the psychological law of enlightened self-interest. If men are properly brought up they will follow this law and, one would think Holbach obliged to conclude, will not need any government.

He does not, of course, so conclude, for he was hardly a logician. When he does abandon rhetoric for something like a concrete program, he is far from iconoclastic. Men have in the past always been the dupes of their vicious rulers; history is a long record of crimes and failures. Holbach, like all his fellows, attacks monarchy under the name of despotism. But he is no great admirer of the English constitution; the balance of powers is a balance of selfishness. Indeed in the latter eighteenth century French admiration for the English constitution was vastly lessened by the attack of the rationalist *philosophes* and by heightened national self-consciousness. Some form of popular government is desirable, but Holbach hastens to make clear that he does not mean that the ignorant and irresponsible masses should have political power, but only the merchant, the artisan, the professional man. Here again there comes in the class consciousness of the bourgeoisie. He leans toward individual liberty, even to laissez-faire, for the individual best knows his own interest. The book concludes with a reversion to the idea of the benevolent despot, and an exhortation to princes to let the light of reason prevail.

It should be clear that much of this radical thinking about nature, the rights of man, and the evils of monarchy touches doctrines we now call socialistic. Indeed Montesquieu himself writes that "the state owes to every citizen an assured subsistence, proper nourishment, suitable clothing and a kind of life not incompatible with health" (*Esprit des lois*, bk. xxiii, ch. xxix). Rousseau in the *Discours sur l'inégalité* blames private property for the fall from the state of nature, although in the *Contrat social* he

accepts it as necessary in the modern world. Yet the great political writers of the century do not in the main attack the institution of property; and the socialism to be found often enough in the work of lesser men is moralistic and utopian. There was as yet no large urban proletariat in France, no factory system, no proletarian class consciousness. Therefore there was no driving force behind socialistic ideas. That these ideas, in content essentially the same as socialistic ideas in the nineteenth century, should have cropped up in an environment apparently unsuited to them, makes an interesting problem in the relationship of political speculation to political practise. Here, apparently, ideas feed upon ideas, instead of upon social and economic necessity.

Since one must single out one of these socialistic writers for further analysis, it will be well to take Morelly, so little known in his own time that his chief work was attributed to Diderot, but since acknowledged by socialists as one of the founders of their faith. The *Code de la nature* (1755) constructs from the true principles of morals an ideal society. Man is gifted with so many varied desires, and nature herself is so generous, that if the fruits of this earth were not monopolized by the few through the institution of property, everyone could always have what he wanted. If someone had already eaten up the peaches, the hungry man could turn to the pears. In the state of nature these idyllic conditions obtained, but the first law givers permitted private property and gradually all existing evils grew up. Man, at bottom good, has been corrupted by institutions. Morelly next draws up a code to restore the state of nature, though it is not clear how men are to be made to accept the code; he admits the code could not be accepted in his own day.

This ideal constitution has three fundamental laws: there is to be no private property save in objects of personal use; each citizen is supported by the state; each citizen will labor for the state according to his strength, his talents and his age. There are in addition an elaborate territorial and family organization on a decimal system, provisions for public buildings and city planning, and a scheme for education and police. The whole suggests Fourier's idea of the *phalanstère*, but Morelly lacks completely the psychological subtlety of Fourier. What is particularly interesting in the *Code*, however, is a whole section (pt. ii) in which Morelly tries to find a basis in

fact for his theories. Community of property, far from being a mere deduction from abstract principles, is, he says, a historical fact. Primitive communities did not have private property, and in our own day the Red Indians show how a people can pursue agriculture under a tribal community of goods. Early legislators corrupted European nations by codes of laws which permitted inequality; the best and most socialistic of these early codes, that of Lycurgus, was precisely the one that lasted longest. This appeal to experience may seem to us rather inadequate; but the important thing is that Morelly felt obliged to make it.

Almost all the currents of political speculation in eighteenth century France converge in Jacobinism; yet because Jacobinism was the creed of a political party and hence translated into action, and because its leaders formulated their ideas chiefly under the pressure of parliamentary necessity, historians of political thought have left the subject to general historians like Taine or Aulard, who are perpetually attacking or defending the party instead of analyzing the creed as objectively as possible. Now Jacobinism as a form of political philosophy, though composed of elements familiar to the student of eighteenth century thought, is, like all true compounds, a new element, and not to be understood as a mere sum of its parts. This philosophy is best sought in the writings and speeches of such leaders as Robespierre and Saint-Just. Rousseau's concepts of the general will, the social compact, the rule of virtue have been transformed into a democratic ritual. The metaphysical rights of man become the Declaration of the Rights of Man and are incorporated into the French constitution, where they promise protection to property, freedom of speech and other tangible things. The revolutionary government, said Robespierre, is "the tyranny of liberty against despotism." The opponents of the Jacobins are wrong, and one cannot be free to do wrong. To guillotine them is to prevent them from doing wrong—that is, in a sense, to free them. The general will is not the will of all, but the will of all who possess virtue—in theological terms, all who are in a state of grace. The external signs of this state of grace are outlined by Robespierre and Saint-Just: the unified nation state; a republican form of government; public worship of the Supreme Being; obligation of all to serve the state, particularly in war; simplicity and decency of manners; the absence of extremes of wealth and poverty, but with private property

and private commercial enterprises; universal education and hence universal suffrage, save of course for non-Jacobins. Robespierre's own standards of conduct were far too puritanical to have been applicable to French life, even had his political methods been wiser, and the failure of the Jacobin republic was inevitable. But the essential ideas of Jacobinism have influenced French and even other governments ever since.

All the representatives of French political thought just considered were hostile to the established order. Political thought in England, where political issues could be fought out in Parliament instead of in the press, and where social issues seemed less serious than in France, was less one-sided. Conservatives like Blackstone and Johnson were even more read than radicals like Price and Priestley. Those who are fond of distinguishing national differences will easily find other ways in which English political thought of the period had characteristics of its own. In method, however, there is little difference between eighteenth century French and English political thinkers. Both schools, indeed, went about the study of the social sciences in much the same way—a fact to which we shall later return.

David Hume was in politics a conservative; he was, however, a rationalist and a polite anticlerical. Had he been born a French citizen, circumstances might have overcome his temperament and made him a reformer like his friends the *philosophes*. But in England fashion was not unkind to conservatives. He never produced a systematic treatise on politics, but his *Political Discourses* (1752) contain some very interesting speculations. He thinks that politics may be reduced to a science, and a mathematical science at that. But the sort of scientific laws of politics his study afforded him may be judged from this one: "That an hereditary prince, a nobility without vassals, and a people voting by their representatives, form the best monarchy, aristocracy and democracy" ("That Politics may be Reduced to a Science" in *Essays Moral and Political*); and in another essay ("Of Civil Liberty") he admits that, even were the art of reasoning more perfect than it is, our paltry three thousand years of history do not provide us with 'enough materials to make scientific conclusions.

Hume points out how in his England each party has built up a philosophical system "to protect and cover that scheme of actions, which it pursues" ("Of the Original Contract" in

Essays Moral and Political)—an anticipation of the modern psychologists' "rationalization." He attacks both the social contract, which he says is ridiculous if, as with Locke, it pretends that all government at all times depends on the voluntary consent of the governed, and the divine right of kings, which he shows can mean only that the divine power has instituted kings as it has instituted constables, and that therefore the authority of both king and constable is equally divine. We have finally left as an explanation of why men obey in civil society only mere custom or habit, which is to say little more than that men obey because they obey. Hume's politics, in spite of scattered aphorisms which are often very penetrating, is as bankrupt as his epistemology. He did, indeed, construct an ideal state ("Idea of a Perfect Commonwealth" in *Political Discourses*), which he would not establish by any violent means but which he is so sure is in accordance with the laws of politics that once established it ought to prove as near immortal as anything in this world can be. Yet even where Hume appears most abstract and rationalist, he is often, like so many eighteenth century writers, curiously near to facts. He proposes, for instance, a "court of competitors," composed of defeated candidates for his senate who shall have polled one-third or more of the votes of their constituencies, and gives this court power to criticize and impeach senators. We must remember that Hume wrote in the infancy of the party system, when most publicists considered parties as troublesome factions. He has gropingly seized the idea of "His Majesty's Opposition."

Of the school of writers who defended the English constitution as the best type of government actually realizable, the Genevan Delolme will serve as the best example. His *Constitution of England* (1775) was for a long time almost as popular in England as Blackstone's *Commentaries*, and illustrates the essentially conservative, if Whiggish, view that the eighteenth century compromise in English government deserved to stand as a pattern for the political efforts of mankind. Delolme starts with the important assumption that "it is upon the passions of mankind, that is, upon causes which are unalterable, that the action of the various parts of a state depends" (introduction). His book is an elaborate, and often acute, analysis of the machinery of the English government seen as an elaborate device for neutralizing the evil passions of men by a system of checks and

balances which allow the good passions as free play as possible. He sees the great part the lessons of experience have played in English politics, and insists that experience, not abstract reason, must be our guide in such matters. But though he claims to follow English lawyers and derive his "rights of Englishmen" empirically (bk. i, ch. iv), it is hard to distinguish these rights as he formulates them from the celebrated rights of abstract man. What is most interesting in De Lolme's work is his complete failure to see the real significance of the facts he has carefully observed. The party system, the true nature of the royal prerogative, the union of "executive" and "legislative" powers in the cabinet, all escape him. Writing at the time of the Wilkes case and the quarrel with America, he could describe the English political system as perfectly adjusted, and could completely ignore the symptoms of grave social unrest evident in the rise of Methodism. These errors, like so many similar errors in eighteenth century political thought, lie not in a wilful ignorance of facts, but in a preconceived and dogmatically maintained interpretation of the facts.

Jeremy Bentham, in spite of his radicalism, appears as a thoroughly British political thinker, presumably because he attacked with violence the concepts of natural rights and social contract appealed to by the French revolutionists. His first work, the *Fragment on Government* (1776), however, exposes these fallacies in the work of a countryman, Blackstone. *The Principles of Morals and Legislation* (1789) is a working out in these fields of the great principle of utility, already announced in the previous work. Bentham's most active period of political writing lies in the nineteenth century; but though his radicalism on political questions increases with age, his methods of thinking do not change.

Men, for Bentham, seek pleasure and avoid pain. A careful observer, studying the actual physiological and psychological effects of the various forms of pleasure on man, can rank these pleasures in a sort of hierarchy and then, with the aid of mathematics, devise a scheme of human life whereby the maximum number of men would enjoy the maximum amount of pleasure. Existing institutions can be subjected to criticism by comparing them with this scheme of things; the critic can discover just wherein society now fails to provide the greatest good of the greatest number.

This principle of the greatest good of the greatest number, explicit in Bentham, is implicit

in most of the other utilitarians of the time—Paley, Butler, Hume, Holbach. Bentham, however, pursued into all manner of fields—criminology, jurisprudence, constitutional law, economics, education—the guiding principle of utility. In many of them his work has been very fertile in practical results. Yet curiously so wise a guide as utility led to the same goal as that most foolish of guides, natural rights. Bentham's program was much the same as that of the French revolutionists—a republic; universal manhood suffrage, annual parliaments, abolition of the House of Lords, the ballot, codification of the law, secular education and freedom of speech and trade. The explanation of this coincidence is partly that the defenders of natural rights maintained that these were rights to pursue happiness and avoid pain without diminishing the happiness or increasing the pain of one's fellows—that is to say, they based rights on utility. But a more profound explanation is that the real criteria by which both Bentham and his natural-right opponents judged human actions were the same. Bentham carefully appraised the value of human pleasure, on the whole much as a thoughtful Protestant would do. Faced with the bewildering complexity of the world, he tries to simplify it and make it a neater and a nicer place. This is exactly what the French reformers tried to do. Both have a set of values which serve to clothe the abstractions "utility" and "natural right"; and these values are essentially those of the Protestant reform. Utility may seem at first sight, and in the hands of some thinkers may really be, a principle close to common sense and worldly things; in the hands of Bentham, in spite of the many tangible changes it helped to bring about, it becomes quite unworldly and unreal.

Bentham, like the Jacobins, would hold the individual to the moral and political compulsion of a republic of virtue. One hesitates, if only out of respect for tradition, to call him a collectivist; but he was certainly no anarchist. The privilege of providing modern Europe with the first political anarchist was, indeed, reserved for the land of political compromise and illogic. William Godwin, more courageous than his French masters, followed up his assumptions to their bitter and logical end. His *Enquiry Concerning Political Justice* (1793) is based on a touching, if un-English, faith in reason and in the perfectibility of man. Men's passions are under the complete command of their intelligence; their intelligence is capable of receiving the com-

mands of reason; the commands of reason are always exactly fitted to the necessities of the moment. Therefore it follows that only reason, freely working within his mind, should command a man to do something. That a man should oblige his fellow man to act according to reason is superfluous; that a man should oblige his fellow man to act contrary to reason is unjust. Similarly no man should be obliged to obey a written law which, if it applies to the case, is superfluous and which, if as is most likely it cannot apply to a case uniquely a combination of circumstances, is unjust. Therefore there must be no interference by force with a man's will; we may, indeed we must, reason with him, and then of course he will act rightly. Godwin has considerable trouble explaining how so many men in his day have lost this complete possession of reason. He is not very clear on the subject but implies that so many human actions became habitual that men ceased thinking about them, and a partial atrophy of reason set in. The remedy is to set our minds at work continually revising our beliefs. In the present order, of course, vicious institutions keep many men poor and ignorant.

Godwin's anarchism is complete. The family naturally falls before it. Private affections cloud the intellect, and prevent our treating all human beings alike according to the dictates of reason. "The abolition of the present system of marriage," he believes, "appears to involve no evils" (*Political Justice*, 4th ed., 2 vols., London 1842, vol. ii, bk. viii, ch. viii, p. 244). Even voluntary cooperation, as in musical concerts, seems evil to him. Naturally the state, which implies a cooperation in part involuntary, cannot stand. Godwin finds that all government—monarchy, aristocracy, democracy—rests upon the fraudulent assumption by certain men of the power to substitute their wills for the free thought processes of their fellows. The pretensions of a representative assembly to decide matters with the authority of its constituents are ridiculous. Godwin ends by reducing government to a minimum of purely local policing necessary to prevent the evils of anarchy (the word anarchy having bad connotations for him, he does not use it to describe his own system). *Political Justice* may of course be dismissed as the culminating absurdity of the method of deducing a political system by abstract logic from unexamined premises. The present renewed interest in the book, after a century of neglect, is hard to ex-

plain. Perhaps our social scientists are unusually anxious to profit by the mistakes of their predecessors; perhaps Godwin's philosophic anarchism flatters underlying human desires increasingly unattainable in the modern world.

The criticism generally leveled against American political development, that it has not produced political speculation of a high order, is certainly not true of the eighteenth century. If only because of the necessity of working out the relation between the federal and the state governments, the American experiment would be important for the political theorist. Out of the mass of interesting pamphlet literature on the rights of the colonists, the rights of man and the proper form of the new government there emerge particularly the names of Hamilton, Jefferson and John Adams. One general caution must be observed in any study of these men. America has never quite been Europe, and Jefferson himself proves the existence of an opposition even at this time. But Europe was not yet condescending, and the superiority which certain Americans cherished was one based on their nearness to nature—to nature in the eighteenth century sense, the mother of philosophy and natural right. One cannot of course leave Braintree out of John Adams, or Piedmont Virginia out of Jefferson; but as political thinkers and especially in a rapid survey such as this, they are best seen as contributors to a body of thought common to the western world. They belong quite simply to the age and company of Blackstone and Bentham, Mirabeau, Condorcet and Beccaria.

John Adams, both as a politician and as a political thinker, presents certain obvious and often remarked analogies with Burke. For neither of them can there be any question of genuine apostasy from political beliefs founded in conscience. Adams' *Defence of the Constitutions of Government of the United States of America* (London 1787-88) and his *Discourses on Davila* (written as newspaper articles in 1790, published in book form, Boston 1805) stand as the assertion of these beliefs, and it is idle to fling at him bits of his writings of the seventies in apparent contradiction of them. These pamphlets, together with some of the writings of Calhoun, are perhaps the best examples to be found in American thought of formally theoretical political speculation. With their apparatus of classical learning, their wide range of reading among the proper philosophers from Plato on, their clear-cut generalizations, their aristocratic

prejudices, and their curiously personal quality which can perhaps be described, in a villainous paradox, as a sort of cold gusto, they seemed to the nineteenth century rather old-fashioned. Today, now that some of their qualities are again in good repute, they seem less remote.

Adams here is definitely a conservative. Men are not born equal; fitness in each sort of human activity is the gift of the few. Obviously even government should be conducted by the fit. His well-known definition of an aristocrat, unfortunately too long to quote (letter to John Taylor, *Works*, ed. by Charles Francis Adams, 10 vols., Boston 1856, vol. vi, p. 457) is an excellent example of his style and thought. History shows him that democracies can be as tyrannical as absolute monarchies, in that they make possible the tyranny of the majority over the minority. The people are quite as given to luxury as their betters; luxury is self-indulgence, and the footman is as fond of gin, porter and pudding as his master is of burgundy and ortolans (*Defence*, vol. vi, p. 94). He admires the English constitution, and believes in the necessity of checks and balances, of which he discovers eight in the American constitutions. We cannot follow further into the details of his thought, of which the foregoing must serve as examples. The roots of his conservatism (if conservatism be taken to mean a distrust in the capacities and intentions of the ordinary man) lie probably in Calvinist Christianity; yet in some ways Adams' conservatism seems less built out of mystic religious experience and more out of common sense and a politic acceptance of the world than Burke's. In method, certainly, Adams is far from the abstract, geometrical school denounced (and partly invented) by Taine. He has at command much apt and picturesque detail; his generalizations are often made with dogmatic warmth, but they are never empty and abstract.

Hamilton stands today in symbolic opposition to Jefferson. Yet his most important political writings, the *Federalist* (1788), in collaboration with Madison and Jay, and the letters in defense of Jay's treaty, signed "Camillus" (1795), do not as directly contradict Jefferson's fundamental political philosophy as do Adams' pamphlets. Hamilton, however, was directly identified with the American business and financial aristocracy, and helped to formulate their characteristic attitude in politics, an attitude which has on the whole been that of American conservatism ever since. Briefly Hamilton may be said to pass over so lightly the assumptions of the natural rights

school that one might almost assume he accepts them, and to devote his chief attention to getting the government to working in the traditional ways of a strong and efficient plutocracy. This does not detract from his originality or his sincerity. Hamilton supplies what Adams lacks, a certain sense of political contingency. The *Federalist* is of course a classic piece of controversial writing, and one which really seems to have decided the controversy. But it is much more than that. It is one of the best examples in the history of thought of the interaction between political speculation and the necessities of actual politics. One realizes, watching Hamilton struggling to adapt them to his needs, what currency such generalizations as the separation of powers, rotation in office, government by the consent of the governed, the social pact, natural rights and others of the same sort had at the time. In the reaction against the view of the American constitution as struck off from the mind of man, we have perhaps gone too far. The fact is that the American constitution, like the French constitution of 1791, was deliberately framed, and framed in a society where interests, habits, traditions and ideas were competing in extraordinary freedom. The *Federalist* otherwise could hardly have been written.

Jefferson has left even less systematic political writing than Hamilton. Nevertheless his state papers and his correspondence form a body of political thought which, despite the derivative nature of its basic assumptions, has a high degree of originality. Jefferson had a universal curiosity and an experience of all sorts of knowledge, a feat still possible in his century. He had the gift of the catching phrase (witness the Declaration of Independence) and of political aphorism. But there was something else. Jefferson's political philosophy was on the whole that of the French theorists before the revolution—he trusted the common man, thought men more nearly equal than not, especially in virtue, distrusted a strong central government, in which the common man could not directly participate, and which would therefore soon become an oligarchy, and wished the necessary minimum of government to be conducted in small local units. But this philosophy he arrived at by observation of the farming communities about him. He never believed it workable in Europe. "It is my principle that the will of the majority should prevail . . . this reliance cannot deceive us as long as we remain virtuous . . . When we get piled upon one another in large cities, as in

Europe, we shall become corrupt, as in Europe, and go to eating one another as they do there" (letter to Madison, Dec. 20, 1787). America was the elect, not of God, but of philosophy.

This feeling of America's mission, which has colored, sometimes garishly but never meanly, American patriotism ever since, gives substance and reality to Jefferson's abstract principles. The America in which he hoped to realize them is dead. The central government is stronger, and certainly more ambitious, than most European governments, local government is devolving on city managers, and the urban population outnumbers the rural. But the principles remain, and we still hold certain truths to be self-evident. Would Jefferson, were he alive? The answer is not easy, for his was a surprising and complex personality, and seems uneasier in others' formulae than in his own. The lover of his fellow men could write: "The tree of liberty must be refreshed from time to time with the blood of patriots and tyrants. It is its natural manure" (letter to Col. Smith, Nov. 13, 1787).

II. Italy continued to the end of the eighteenth century in a state of political helplessness. Her numerous petty governments were usually backward and often cruel; and yet the Italian people did not of their own initiative produce a political revolt, as did the French, nor an intellectual and literary revolt, as did the Germans. It is one of the numerous difficulties faced by the intellectual historian in his attempt to relate his subject to social and political history that the contribution of Italy to eighteenth century thought, and particularly to thought in the social sciences, should none the less be considerable. Perhaps the best explanation is that Italian thinkers were an *élite* writing under French and English influences, and anxious for a European, rather than an Italian, reputation.

The Marquis Beccaria was both the pupil and the teacher of his French masters, the *philosophes*. His *Dei delitti e delle pene* (1764) was soon translated into the principal European languages, was incorporated into the program of radical thinkers everywhere, and actually did influence such practical reformers as the Englishman John Howard. Beccaria's condemnation of torture and secret accusation in criminal trials, and his demand for reasonable and clear penalties in place of the extreme and therefore frequently evaded punishments com-

mon even in English law of the time, have now been universally translated into practise. His condemnation of the death penalty has been less universally accepted. His book is a mixture of fashionable rhetoric on natural rights, of equally fashionable humanitarian sentiment and of effective reasoning. And for a pioneer work in criminology it is remarkably sound. Beccaria was one of the first to make clear that the prevention of crime is the purpose ultimately served by the punishment of crime.

The book has pretensions to be more than a treatise on crime and punishments. Beccaria pins his specific attacks on abuses and his suggestions for reform to a system of generalizations about society that mark him as an eighteenth century man. The laws which are born of the social compact exist for the sake of "la massima felicità divisa nel maggior numero" (ch. i). Men are moved by self-interest, and therefore yield up to society only that portion of their liberties necessary to secure peace and tranquillity in society. The sovereign created by the compact can wield a power measured by the aggregate of liberties so yielded up. The right to punish—to deprive a man of all his liberties—is thus limited to the minimum exercise calculated to restrain men from breaking the social compact. All punishment beyond this is unjust and contrary to nature. Again, to take a representative passage: "For a punishment to obtain its effect, it is sufficient for the evil of the punishment to exceed the good of the crime, and in this excess of evil must be calculated the infallibility of the punishment and the loss of the good anticipated from the crime" (ch. xv). Although Bentham would have objected to phrases about rights and compacts, he must have accepted not merely Beccaria's practical conclusions but much of his intellectual approach.

The Neapolitan, Gaetano Filangieri, although he lived under what was perhaps the worst of Italian governments, and was even employed by that government, produced one of the most radical of eighteenth century political treatises. His *Scienza della legislazione* (1780-85) set out to continue and improve the work of Montesquieu. The *Esprit des lois* had been too much concerned with what the laws were; Filangieri's work set out to show what, with due regard to historical and geographical differences, as well as to the principles of reason, they ought to be. There is little originality in the book; its interest lies in the completeness with which Filangieri applies to all the subjects he con-

siders—economics, general jurisprudence, criminal law, education, religion—the test of conformity to reason. He is no anarchist and no collectivist, and he is guided in his specific suggestions for reform by no fundamental philosophical assumptions beyond the characteristic eighteenth century utilitarian psychology. His radicalism comes from the application to each problem of a practical sense which is yet far from common sense. He is the extremist among the theorists of benevolent despotism. Yet Filangieri abounds in occasional bits of wisdom, and now and then gives way to sensible doubts. He has an interesting passage (bk. iv, ch. xxxviii) on the method of the social sciences, where he points out that in chemistry elements may be isolated, weighed and measured, but that in politics, even though it may help to assume that causation operates as in the physical sciences, we cannot apply the methods of mechanics and mathematics.

The Enlightenment in Germany was rather a moral and philosophical movement than a political one, and those who reacted against it, like Kant and even Herder, belong rather to the intellectual history of the nineteenth century than to that of the eighteenth. Germany was still a collection of states under the remains of the mediaeval empire, she had suffered an unbelievable setback in the Thirty Years' War, her upper classes were slavish imitators of French court manners, and her middle classes prosperous enough, or custom ridden enough, to accept the political order without complaint. The Enlightenment is indeed a movement parallel with the similar rationalist movements in France and in England; but in Germany it is singularly superficial and devoid of explosive power. German political thought continues seventeenth century natural-rights philosophy (which gets reduced to a sort of scholasticism) and grafts upon it certain importations from the French, and an insistence on the omnipresence of the state which is explicable enough in terms of German political experience, but which hardly jibes with some of the premises of the natural-rights philosophy.

Of these philosophies of the Enlightenment Christian Wolff may be taken as a type. His *Vernünfftige Gedanken von dem Gesellschaftlichen Leben* (1721) and his *Jus naturae methodo scientifica pertractum* (1740-48) form a system based on the equality of men before nature. Differences in rights are acquired, the results of historical growth. By nature, however, all men

have the same rights and the same duties. No man has the power to interfere with other men. By nature all men are free (*Jus naturae*, ch. i). The aim men pursue in the state is *Vollkommenheit*, perfection or self-realization, which can never be attained, but toward which men are gradually moving. Here are liberty, equality and progress all in black and white. But for Wolff these are apparently the necessary and philosophic abstractions with which one approaches the study of politics. His actual program is purely a theory of the benevolent despot, and gives an extraordinary scope to state action. One cannot even say that he is consistently in accord with the rationalist philosophers who would use state action to create a new society based on logic and not on history. He is for the old guilds, limitations on the number of apprentices, and against freedom to emigrate. He defends censorship of the press, and even goes so far as to admit a mild and humane use of torture in criminal trials. Wolff's theories of the origins of society take on the fashionable form of the compact. The government created by the pact, however, is bound to conform not only to the laws of nature but to the fundamental laws agreed upon when the society was formed. If these laws are violated, the people have the right of resistance. From Wolff's whole political writings it is perhaps not unfair to conclude that the natural-rights formula had no necessary connection with revolution; it had become so universally accepted that it had no practical implications.

The beginnings of the peculiarly modern and literate type of nationalism may be seen in German literature of the latter half of the eighteenth century. In political writing the followers of the French had never been unchallenged. Justus Möser, who spent his whole life as lawyer and judge in the little Westphalian town of Osnabrück, is only one of many eighteenth century publicists in Germany who repudiated the new cosmopolitanism. Möser wrote an introduction to the history of Osnabrück, in which the value of social, as opposed to purely political, history is emphasized, as well as numerous political essays, the *Patriotische Phantasien* (1778). He is a traditionalist, a conservative who believes in defending the good old Germany of the soil. He detests modern reformers who would abolish history in the name of reason. In point after point he opposes the individualistic and utilitarian tendencies of the time, even when they are turned into humanitarian channels.

With the natural rights of illegitimate children, for instance, he has no sympathy. Society owes them nothing, for they menace the most sacred human institution, the family. Möser, if he insists that history and not logic is the first teacher of the political philosopher, can nevertheless hardly be called a realist. For he finds in history a vague ideal of Teutonic freedom, antedating the abuses of the Middle Ages—the freedom of German tribesmen uncorrupted by inequality of property holdings.

There are, however, political thinkers who seem even more completely opposed than these German patriots to the normal way their contemporaries went about the study of politics. No account of eighteenth century thought would be complete without the mention of two men who yet scarcely fit any of the commoner generalizations about it—the Neapolitan, Giambattista Vico, and the Irishman, Edmund Burke.

Vico, whose great work the *Principi di una scienza nuova intorno alla natura delle nazioni* (1725-44) was little known until the nineteenth century, is often given credit for founding the philosophy of history, a form of intellectual activity highly developed in the days of Hegel and Comte, but held by professional historians in disrepute until the present moment, when it bids fair to become popular again as a methodology or synthesis of the social sciences. In this field Vico developed a theory of the flux and reflux of civilization through different societies—Greece, Rome, the Middle Ages—which is elaborately worked out, with a somewhat scholastic fondness for the figure three. Vico finds three sorts of government which succeed each other in order of time in all societies: the divine, when men make gods to rule them; the heroic, when heroes, demigods, rule them; and the human, when intelligence rules them and they devise laws and the idea of civil liberty. This is the height of civilization a given society can attain. Reflux begins, men become overcivilized, and the third form reverts to the first. Whether Vico thought this process was an eternal repetition, or whether he believed each cycle had benefited from the previous ones, is not wholly clear. Vico also figures as a forerunner of Montesquieu in the sociological approach to the study of law, though it is to be doubted if the French philosopher could read the *Scienza nuova*. And there is, especially in Vico's careful study of Roman law and early Roman civilization, a great deal to justify this statement. But perhaps Vico's general philos-

ophy, and in particular his theory of knowledge, is more important even for the social scientist than the results of his investigations into historic fact, which were partly invalidated by his peculiar superstitions, such as his fondness for triads, by his religious mysticism and by his lack of tools for research. His theory of knowledge, however, definitely anticipates the nineteenth century reaction against Cartesianism which was to be so important for the social scientist. Vico refuses to accept the Cartesian *cogito ergo sum*, and the resultant tests of truth by clarity and of scientific method by mathematics. He identifies *knowing* with *creating*. God alone has perfect knowledge, since God alone created all things. But of the feeble knowledge vouchsafed man the best, apart from divine revelation, is that which corresponds to the field in which he exercises his creative power. Now man has created the society he lives in, though he has not created the universe about him. Hence our best knowledge is not of mathematics and the mathematical sciences but of history and the historical sciences. It is not abstract speculation that is valuable, but the hard fact, the individual; it is not the superficial similarities of things the thinker should pursue, but the fundamental differences. Real knowledge is a conquest to be won literally by the sweat of one's brow. Vico's whole work, in the very confusion and trouble into which his restless desire to get beyond the smoothness of thought into the roughness of things causes him to fall, is a striking contrast to the cocksureness of much eighteenth century thought.

Although Edmund Burke never wrote a formal treatise on politics, there are more political ideas in his speeches and letters, and especially in his pamphlets on the French Revolution, than in most treatises. He is, however, a difficult man to get into a few words. His complexity is one of depth as well as breadth, and sets him off even more completely than Vico from his century. Of his breadth there is sufficient evidence in the fact that political thinkers of such different allegiances as the liberal Morley, the conservative Hugh Cecil and the laborite Harold Laski should all find in his philosophy important elements of truth. Of his depth the sober analysis whereby in 1790 he predicted the Napoleon of 1804 should prove an adequate example. Burke denied the existence of rights and defended political expediency; but he was no utilitarian. He distrusted the common man and believed in aristocratic rule; but he was not an

unimaginative standpatter. What lies at the bottom of Burke's thought, however, makes him in 1790 almost a heretic among publicists; he is a Christian, a pessimist and no believer in progress. He lived too much in the world, of course, not to have uttered at times words which seem to contradict this. But any thorough study of his whole work will bring out these fundamental conservative beliefs. To Burke man was a fallen creature, not to be redeemed on this earth; to give him freedom was to unleash the brute. Civil society and law, tradition, custom, habit, loyalty operating within it almost miraculously make men behave far better than a psychological study of the isolated individual would lead one to think possible. But society represents at any moment a delicate equilibrium between rest and unrest, and if you disturb it, as the French are doing, to rewrite all the laws according to reason, you destroy the equilibrium, and the brute in men, which the old laws and the old loyalties have put to sleep, is awakened and will have no respect for your new and perfect laws. Burke's pessimism enabled him to see things most of his contemporaries were too hopeful to see, and his literary skill has embodied his observations in aphorisms scattered throughout his works. This, and a certain moral earnestness that seems to underlie even the ravings of the *Regicide Peace*, may account for the respect which men of such different political faiths have felt for the writings of Burke.

III. Economics, even in the latter half of the eighteenth century, was hardly a special science. Most men who wrote on economic subjects also wrote on other subjects, or incorporated their thoughts on economics into political or literary works, as, for example, Montesquieu, Filangieri and Hume. The originality of the *Wealth of Nations* is partly one of form; it is the first complete systematic treatise on economics in the modern sense written by a thinker of the first rank. Of course the day has long gone by when Adam Smith had no predecessors and few contemporaries. Mercantilists, cameralists and physiocrats (*supra*, p. 121-24) may now be admitted to have contributed much to the methods, the material and even the theories of the most scientific of the social sciences. In the confusion of writings on economic subjects in the eighteenth century it is extremely difficult to say, "This went into the making of classical economics, and this did not," or, "This is orthodoxy, and this is heresy." That dull

mercantilist, Steuart, has interesting anticipations of Malthus on population; Italian mercantilists such as Genovesi do useful work on monetary theory. We shall therefore mention hastily some British thinkers who are perhaps better catalogued as "forerunners of Adam Smith" than as members of already existing schools, and then turn to the founder himself.

Mandeville, though he fell into the shocking make-work fallacy, yet brings forward in his *Fable of the Bees* (1705; enlarged ed. 1714) a theory that private vices make public virtues, that is, that men working selfishly in their own interests will unconsciously cooperate in working for the public good. Josiah Tucker, dean of Gloucester, wrote many pamphlets on politics and economics. It would appear from the point of view of a later period that he kept his politics and economics in separate parts of his mind, for he was both a conservative and a free trader—a combination, however, not as surprising in eighteenth century England as it would have been in 1840. As a Tory he thought the American colonists' arguments about their indefeasible rights sheer nonsense, but as a free trader he came to the conclusion that the colonies were a nuisance and should be cast off. Wars for the sake of trade, he predicted, would one day seem as absurd as the crusades. Hume in his economic writings is as clear-sighted and as fragmentary as usual. He sees at once the fallacy of the mercantile position on the accumulation of money, an attempt which is as ridiculous as trying to keep water above its natural level. He emphasizes the stock of labor as the true source of wealth. His monetary theory is surprisingly sound, and even his often criticized remarks about the stimulating effects of rising prices are true in themselves. Smith himself owed much to Hume, whom he knew and revered, as well as to his teacher Francis Hutcheson, to whose chair of moral philosophy at Glasgow he succeeded. The latter's influence upon Smith was no doubt largely in the field of philosophy; nevertheless Hutcheson mixed economics with ethics, and in his *System of Moral Philosophy* (1755) has familiar ideas on the division of labor, value and interest. He makes a clear distinction of the sort Smith was later to make between value in use and value in exchange (*System*, vol. ii, p. 53).

The *Wealth of Nations* (1776) shares with the work of the physiocrats the honor of elevating economics from a narrow study of the mechanism of commerce to a genuine discipline,

to a study of the production and distribution of wealth. In a sense everything of importance Adam Smith wrote has been supplanted. In the more complicated reaches of economic theory—including value, rent, money, population and much else—the successors of Smith have gone far beyond him, and even the so-called “classical economists” from Ricardo to J. S. Mill differ from him in many ways. But Adam Smith did bring out clearly many ideas about the division of labor, the distinction between value in use and value in exchange, between wages, interest, profits and rent—to give merely a few examples—which have since become commonplace. He brought out clearly in his treatment of the details of economic life certain principles whose political, and even scientific, influence is still very great—notably that of the non-interference of government in business (summarized, though not by Smith himself, as *laissez-faire*) and that of free trade. Finally, although his language is the literary tongue of his century and although he therefore hardly appears as an inventor of a special scientific terminology, he marked out much of the ground which economics (and especially economics as distinct from sociology) has since occupied. For these reasons he deserves the salient position among economists that common opinion has always given him.

Adam Smith serves as well as lesser men to point the commonplace that thinkers depend on their physical environment. Just as Quesnay, country-bred and citizen of an agricultural nation, stressed land as the ultimate source of wealth, so Smith, citizen of a great commercial country already stirring with the industrial revolution, stressed labor as the source of wealth. The labor of artisans and business men seemed to the physiocrats inferior and even “sterile” labor; to Adam Smith the capitalist and the business man are integral parts of the machinery for the creation of wealth. But our beliefs depend partly on the beliefs held by our contemporaries, and of this somewhat neglected commonplace Adam Smith is also a good example; moreover the question of Smith’s affinity with other eighteenth century thinkers, and especially that of his ideas of a natural order with similar ideas held by other workers in the social sciences, is one that is very close to the aims of this survey.

Some commentators have discovered an antinomy between the *Moral Sentiments*, where Smith founds morality on human sympathy, and the *Wealth of Nations*, where he founds eco-

nomics on human selfishness. Such a view is unjust, for to Smith sympathy and self-interest are simply complementary aspects of natural human activity. Sympathy is a kind of inverted self-interest that serves to check us automatically in our relations with our fellow men. When men act as they want to, their actions, isolated and anarchical though they may seem at first sight, are really in accord with an underlying scheme of things, a natural order established by Providence. The careful investigator into men’s economic activities, for instance, will find beneath the apparent disorder of hundreds of different enterprises, the higgling of the market, the conflict of thousands of interests, the clear principles and admirable order so well described in the *Wealth of Nations*. Governments, for lack of true knowledge, have often interfered with this process. But they have added real and harmful disorder to the merely surface confusion of natural economic life, and have thus prevented the designs of Providence from working themselves out completely. Therefore governments should in general refrain from interfering with the economic activities of their subjects. In the next century critics like Cliffe Leslie held that Smith’s belief in a natural order was arrived at *a priori*, that it was a part of the false thinking common to his century, and that it therefore vitiated somewhat the enormous amount of direct observation embodied in the *Wealth of Nations*. As this is a point which involves in general the methodology of the social sciences in the eighteenth century, we shall return to it later. But it may be remarked here that Smith himself did not hold as rigidly to the principle of *laissez-faire*, nor insist as warmly on absolute, immutable economic laws, as did some of his nineteenth century successors.

The most interesting book on economics published in France in this period is Richard Cantillon’s *Essai sur le commerce* (1755, but written about 1730). Cantillon was an Irishman who had made a fortune in banking in Paris, and his little book shows an extraordinary grasp of practical detail as well as much speculative ability. Though Adam Smith refers to it, the book was little known until Jevons rediscovered it and held it up as the most complete of the forerunners of the *Wealth of Nations*. Cantillon’s opening sentence is in the best style of the eighteenth century, clear in definition and compressed: “La terre est la source d’où l’on tire la richesse; le travail de l’homme est la forme qui la produit; et la richesse en elle-même n’est

autre chose que la nourriture, les commodités et les agrémens de la vie" (pt. i, ch. i). Note that in that one sentence Cantillon emphasizes equally the role of land and labor (which neither the physiocrats nor Adam Smith did), and that he gives the modern, as opposed to the mercantilist, definition of wealth. Cantillon's theory of value (pt. i, ch. x) shows the same merits of brevity, apt illustrations and ability at generalization. He concludes that "intrinsic value" is measured by the land and labor involved in production, allowing for the goodness or product of the land and the quality of labor. He then distinguishes between "intrinsic value" and market values. He arrives at these generalizations by studying Brussels lace, for instance, and he has constructed elaborate statistical tables to show how the amount of labor involved in lace making, together with the cost of material, etc., about equals the price. Cantillon has interesting passages anticipating the study of the role of the entrepreneur, is good on money, and extremely good on international trade. The essay was apparently written about 1730, nearly half a century before the *Wealth of Nations*. This fact suggests that, if the influential works in the history of thought are dependent on social and economic conditions for their success, the human mind itself is perhaps somewhat less limited, and may sometimes steal a march on its environment.

Most of the continental economists of this period may be classed as physiocrats or mercantilists, and need not here be considered. But a word should be said about Condillac, who in his *Le commerce et le gouvernement, considérés relativement l'un à l'autre* (1776), though not otherwise very original, does anticipate the psychological theory of value. We value a commodity because of the use we think we can get from it. Scarcity gives a commodity greater value, and abundance gives it less, but this value is based less on its actual scarcity or abundance than on the opinion we form of its scarcity or abundance (pt. i, ch. i).

IV. The greatest historians of the eighteenth century are included in the school usually called "rationalist" (see Section VI). But there are other, and as far as the later writing of history goes, more important ways of approaching history than that exemplified in the elegance and speculative acuteness of Hume or Gibbon. By 1800 great progress had been made in the accumulation and criticism of source material, and in

the writing of social, as opposed to merely political, history.

The *Acta sanctorum*, going back in conception at least to Heribert Roswedye (1569-1629), and treating the lives of all saints under the day consecrated to their worship, had by 1786 proceeded from January 1 to October 11. Their great founder was John van Bolland (1596-1665), and the patient monks who worked with him and after him in what still remains one of the greatest monuments of scholarly cooperation are known as the Bollandists. The level of the different lives varies greatly, but the *Acta* as a whole contain an enormous amount of material, not merely for church history, but also for political, constitutional and social history of a period which, in the eighteenth century particularly, was very little known. It was one of the collaborators in this work, Daniel von Papebroeck (1628-1714), who began the study of diplomatics later worked out by Mabillon.

To Jean Mabillon (1632-1707), of the Benedictine Abbey of St. Germain des Prés, and to the Maurists who followed him, belongs the credit of working out a whole critical apparatus for the study of historical documents. Mabillon's *De re diplomatica* (1681) sets out criteria for judging the authenticity of original source material, outlines the beginnings of a science of palaeography and even of such very special subjects as sigillography. The Benedictines continued during the entire eighteenth century their careful reconstruction of mediaeval history and the working out of historical method, and in 1765 the monks of the congregation of St. Maur issued their *Art de vérifier les dates*, where scientific methods are first introduced into the confusion of historical chronology. The century often supposed contemptuous of history and fond of glib generalizations and easy synthesis is also the century of painstaking research and of critical establishment of canons for sifting evidence.

This critical spirit appears in other fields of history, notably in those of Greece and Rome. The study of classical antiquity, revived by the great scholars of the Renaissance, suffered from the undue reverence which the humanists had for their subject. In the eighteenth century with such men as Barthélemy and Winckelmann archaeology emerges as a distinct discipline. Vico had begun the search for the social origins of Roman law and had anticipated Wolf on Homer. At the very end of the century Niebuhr inaugurated the modern study of early Rome,

destroying a mass of uncritical ideas springing largely from Livy and kept alive by the current system of education. A book like the Huguenot refugee Thoyras' *Histoire de l'Angleterre* (1724), once extremely popular in England, is representative of much eighteenth century work. It is full of prejudice in favor of the Protestant cause; it is moreover ill-digested, quite lacking in the flow and form of the rationalists. But it is full of material gathered from original sources, and it constantly attempts to show how what are now regarded as national characteristics have a historical origin.

Another contribution of the eighteenth century to historiography is to be found in its interest in social history. It is not, of course, that such history was particularly new. As far as his subject matter goes, Herodotus was a social historian. But what characterizes modern interest in social history is a more or less definite belief that the conditions under which ordinary men live can be scientifically analyzed and therefore modified for the better. This interest is a part of the democratic movement which marks the rise of the middle class. Once that class was established, it began to seek in history some compensation for the dullness of its ordinary life, and the romantic schools of historians arose. But in the eighteenth century history remains sober, whether it deals with kings or peoples. Voltaire's *Essai sur les mœurs* is of course social history, and so is much of Montesquieu. Charles Duclos' *Mémoires pour servir à l'histoire des mœurs du XVIII^{me} siècle* (1751) is an example of much contemporary writing on the borderland between sociology and history. But social history flourished best of all in Germany, with such men as Möser and M. J. Schmidt. A passage from Schmidt's *Geschichte der Deutschen* (1778) has a familiar sound: "Most historians are content to chronicle the changing rule of princes and aristocracies, without bothering about the condition of the people But if at the same time the historian does not consider the degree of national happiness he does not seem to me of much use" (preface).

V. It would be impossible, of course, to include in this essay all the important writers in the social sciences in the latter half of the eighteenth century. No doubt discoveries can still be made, and many monographs are still to be written in this field. For the convenience of the student and the general reader who may wish to

go into the subject for himself, the following list of names is appended. The list is not, of course, exhaustive but, taken with the names already considered, includes what is important in the four chief modern tongues and Latin.

POLITICAL WRITERS:

D'Argenson, Babeuf, Blackstone, Brissot de Warville, John Brown, Burlamaqui, Condorcet, Camille Desmoulins, John Dickinson, Diderot, Cl. Dupin, Adam Ferguson, Sir Philip Francis, Franklin, Frederick II, Abbé Grégoire, Helvétius, Jurieu, Linguet, Mably, Sir James Mackintosh, Madison, Mercier de la Rivière, Mirabeau, Morellet, Otis, Paine, Paley, Price, Priestley, Abbé de Saint-Pierre, Bernardin de Saint-Pierre, Shaftesbury, Siéyès, Thomasius, Vattel, Volney, James Wilson, Mary Wollstonecraft.

ECONOMISTS:

Mostly mercantilists or physiocrats, but the Abbé Galiani and Verri, in addition to those mentioned in the text, are worth looking into.

HISTORIANS (excluding the "rationalists"):

Algarotti, Anquetil du Perron, Thomas Birch, Carli, Gatterer, Grosley, Sir William Jones, William Maitland, Joh. Müller, Muratori, de Pauw, Roscoe, Schlözer, Sismondi, Spittler, Soulavie, Tiraboschi.

No attempt at summarizing in a critical fashion the social-scientific thought of the second half of the eighteenth century can do justice to the subject. Certainly we cannot accept the evaluation of eighteenth century thought by such nineteenth century critics as Taine, although theirs is still the current view. The thinkers of the age of revolutions were, according to this view, imprisoned in an artificial universe constructed out of Descartes and Newton. From Descartes they learned to distrust all knowledge not capable of mathematical formulation. From Newton they learned to seek even in human relations for laws of mechanical causation. Their thought is therefore abstract and inhuman; their conclusions apply only to an artificial man of their own creation, a man as unlike existing human beings as a geometrical figure. Their program of reforms, built to suit this artificial man, cannot apply to human beings. To dangle it before real, imperfect men is highly dangerous, as the French Revolution proved.

Now there is no use denying the element of truth in this criticism of eighteenth century

methods in the social sciences. But in its extreme form this criticism is as far from facts as it believes the eighteenth century to have been. In the first place, it is obviously truer of minor thinkers like Holbach than of great ones like Montesquieu. Again, it fails to take into account the complexity of the intellectual interests of the time, to include Burke, Vico, the German patriots, Adam Smith, the Rousseau who inspired the romantic movement. Even the cruder thinkers, who fell most easily into generalizations about the natural man, were partly led into a false method by a desire to get things done, to arrive at conclusions that would influence their fellow men to action. It is notable that, although much early eighteenth century work is in Latin, almost all work done in the second half of the century is in one of the modern languages. Up to a point, as any study of the Jacobins will show, a certain amount of abstraction is extremely practical as political propaganda. Finally these men were pioneers of a sort, and subject to the rashness and overconfidence common to intellectual pioneers. They were trying to put on paper the lofty aspirations of the growing middle class.

Such explanations—one might almost say, such apologies—are necessary for the normal level of thought which is determined by the "spirit of the age." But it is almost a commonplace that the great men of an age, though they embody its spirit, also transcend it. For such men as Montesquieu, Adam Smith, Rousseau and Bentham no crude formulae about *a priori* thinking can hold. Indeed the whole problem of the use of the deductive method by eighteenth century thinkers is one that deserves a more truly critical treatment than it has commonly received. Certainly the men of the time thought they were appealing to experience. Most of them were willing enough to appeal even to historical experience. The facts which they used to build up their theories may seem to us now insufficient in number and even inadequately established as facts, but as facts they did command the respect of the thinkers who used them. French republicans sought to model themselves on Roman republicans; even the utopian socialist, Morelly,

tried to find socialism in fact in ancient Sparta.

But is not this mere appealing to an arbitrary set of facts to confirm an arbitrary theory, or rather is it not molding fact to desire? No doubt many eighteenth century thinkers saw only the facts they wanted to see. But are desires and hypotheses utter aliens to each other in the consciousness even of the modern scientist? The eighteenth century did at least avoid the error that facts can take care of themselves, that induction is a process that goes on in the mind of the thinker, indeed, but without any active co-operation on his part. What the modern scientist means by a theory or a hypothesis is what the eighteenth century thinker meant by a law of nature. For both, the chaotic, accidental world as it appears to the senses—and even to common sense—can be made to appear orderly to an inquiring and persistent mind. The social sciences today, as well as the physical sciences, are more aware of the complexity of the sense world, more aware therefore of the necessity for careful research; they are more tentative and less dogmatic than in the eighteenth century. There adheres to the eighteenth century idea of natural law something more of ethics and theology than is fashionable nowadays, at least under those names. But the concept of a "natural order" not apparent to the unthinking man is common to both centuries.

What, then, is left of the social sciences in the latter part of the eighteenth century? A great deal of propaganda, of popular writing that first helped arouse a class consciousness in the middle classes, and made great numbers aware of the existence of social problems; a tradition, therefore, of the intimate connection between the social sciences and practical politics; the work of certain great founders, like the economist Adam Smith and the sociologist Montesquieu; a great deal of patient research, an accumulation of facts that can still be used to support theories other than those held by the workers who first uncovered the facts; and, finally, the concept of a natural order for which all science is a search.

CRANE BRINTON

IX

Individualism and Capitalism

I. What were the inescapable facts and ideas which surrounded and impinged upon the senses of the thinkers who formulated social theories in the early decades of the nineteenth century? Before settling down to an examination of that problem we should consider briefly a closely related philosophic question which has accompanied speculation since the days of the Greeks, namely, which is older, the fact or the idea? "In the beginning was the Deed" (*Am Anfang war die That*), we are informed by the poet Goethe. "In the beginning was the Word," we are told by the theologian. The great debate has never been closed to the satisfaction of the contestants, but William James has given us a fair working formula in the declaration that the worlds of fact and idea have evolved together. Their relations are reciprocal and no sword of reason has yet been forged with an edge fine enough to separate them. Whoever would seek to penetrate to the heart of an age or indeed to divide indivisible time into ages must reckon with this instrument of thought.

Undoubtedly new facts are easier to discover than new ideas, assuming for the moment that the two are separable for the purposes of thinking about them. The first use of the steam engine to turn wheels, the first loom driven by power, the first successful crossing of the Atlantic by a ship driven by steam were new facts in the history of the world. But the cluster of ideas associated with each of these facts wears ancient aspects. Indeed the idea that such things could be done was as old as Roger Bacon at least, to make no reference to the use of steam by the Greeks. Yet for the great mass of humanity the appearance of each of the material phenomena mentioned above was a new fact, stirring up old ideas and suggesting new ideas.

There are times in the history of the world when facts almost stand still, when ways of living, working, traveling and fighting change so slowly that thought more than catches up with them—seems in reality to control, rather than to reflect, them.¹ Broadly speaking, such a

period was the Middle Ages. Then again there are periods when new facts come pell-mell upon the world, devastating wars and revolutions, epoch-making inventions, defying old systems of thought, making them appear incongruous with the world of reality and compelling a revision of logical patterns once satisfactory to their possessors. Sometimes these new facts come so swiftly and spread so widely that thought is apparently incapable of reducing them to a system, to say nothing of controlling them in relation to ideas, inherited or novel.

Nevertheless even in such periods of history the relations of idea and fact are still reciprocal. If, for example, modern emphasis on the production of goods seems to flow from the fact of machinery and tends to a secularization of thought, it must be said that the secularization of thought which accompanied the renaissance of pagan learning stimulated interest in this world as distinguished from the next, lending sanction to the enjoyment of goods and thus promoting their manufacture. Long before the Protestant revolt and the rise of Calvinism, to which too large a part of the commercial spirit is now uncritically attributed, secularism was growing in Catholic learning and doubtless would have increased had the quarrels of princes and popes never taken place—assuming for the moment that, given the contemporary movement of ideas and facts, such quarrels could have been avoided by some process.

However closely a new fact of high significance may be related to a pre-existing cluster of ideas, it nevertheless runs like a sword into the old web of ideas. At first it must be considered in terms of those ideas, their logical form and phraseology. It may excite wonder and surprise, produce ejaculations of amazement and incredulity, but when its implications are considered, the nature and purpose of control over it (if any) must be geared up to the inherited stock of opinions, morals, creeds, laws and sayings. Gradually the new fact is worked into

¹ See George O'Brien, *An Essay on Mediaeval Economic Teaching* (London 1920) p. 189 *et seq.*, for changes in scholastic theories of interest and usury accompanying increas-

ing opportunity to accumulate and lend money. Also Edmund Schreiber, *Die volkswirtschaftlichen Anschauungen der Scholastik seit Thomas v. Aquin* (Jena 1913) p. 227 *et seq.*

the old body of thought, effecting changes in it, making some of it obsolete, giving novel direction to the remainder, and suggesting idea patterns which at least have the appearance of novelty. This operation of readjusting facts and ideas requires time; hence there is always a lag between the appearance of an important fact and the formulation of systematic thought about it. And inevitably such systematic thought, being the product of thinkers, bears some kind of relation to the connection of the thinkers with the fact, a connection that may be close, remote, friendly or hostile. Perhaps it is principally for this reason that the political philosophies of countries seem to vary so materially in rhetorical form. For example, when the English middle classes overthrew absolutism in the seventeenth century, the dominant body of inherited thought was religious—hence the Puritan revolution was defended in Biblical imagery; but when the French carried out the same kind of revolution more than a hundred years later, natural science had made such strides that “natural” rights appeared to be more real than the admonitions of the God of the Old Testament.

II. Now the central fact that gave decided character to the decades between the French Revolution and the middle of the nineteenth century was the rapid, almost bewildering, rise of capitalism to a position of dominance in western civilization. The term calls for definition. What is capitalism? Laying aside all collateral issues and going to the heart of the matter, it is a system of production, involving social relationships, in which the primary object is the gain of profit through exchange.¹ Among the primary social relationships created by it is the association of employers and employees in the process, the former as dominant directors and the latter as the source of labor skill and strength. Capitalism is not synonymous with machine industry, although it has flourished most luxuriantly in the age of technology. It is not synonymous with manufacturing; indeed conceivably it might take over the entire scheme of agricultural economy. It is not synonymous with objective capital goods or accumulations of instruments of production, for in that sense feudalism was capitalistic in that it had instrumentalities devoted to production.

Yet wherever this system of production has overtaken the static order of feudalism and

guilds—production primarily for use and exchange at “a just price”—it is accompanied by certain outward signs, material and human: (1) mines, factories, machines, railways, stores, warehouses and other implements of production and banking and systems of credit on a large scale; and (2) owners of the means of production, directors, technologists and laborers ranging from skilled craftsmen to casual workers. The seats of capitalism are in the cities, not the open country. In the main it is employed in the creation and distribution of manufactures. Unlike agriculture and handicraft industry, producing for use or local exchange at a just price, capitalism has apparently indefinite boundaries for expansion. The amount of land available for cultivation is fairly limited (though science works wonders here also), but the area of capitalistic operations has no limits visible to the naked eye. The amount of wealth that can be amassed by it, the number of men and women who can be employed by it, seem capable of indefinite expansion. That is not all. The agriculture of a country is carried on within its geographical boundaries and under its flag, while the capitalism of a nation may carry on operations under many flags in all parts of the world. Conceivably the capital of any particular nation invested abroad might exceed in value the capital invested at home.

In its economic methods and also in its technological aspects, capitalism is essentially rational, involving no mystic elements for guidance in practise or in the increase of goods. The uncertain elements of nature which plagued the agriculturist of the ancient type—rain, drought, insects and declining fertility, to be influenced by exorcism of spirits—do not appear in the capitalist's world. As to the technical aspects of capitalism, there can be no doubts; it is governed by the laws of mechanics and physics which can be expressed in terms of mathematics: mass, weight, extension, number, movement, etc. If capitalism is restricted to its proper economic meaning as a social relation, still its essence is rational. Every operation is based on calculable factors which can be mirrored in balance sheets; extension of plant, raw materials, “hands,” output, prices, sales and profits. Capitalists may pray for riches, but they know that the invocation of saints will not automatically, by some unseen process, make them rich. They may need “psychology” to improve “industrial relations,” but such improvements are reflected in ledgers and registers.

¹ P. Rostock, *Der Ausgang des Kapitalismus*, p. 1-8.

III. The age which witnessed the rise of this system of production to a position of dominance in western civilization is the period of early capitalism. In this connection "early" is a purely relative term, in a strict sense scarcely correct. In essence early capitalism is no different from late capitalism, for the system of production does not vary in itself, but it takes time for capitalism to spread over a wide area of a nation's economy and at last reach a position of dominance. That is self-evident; hence the justification for the application of the term "early capitalism" to the period of history here covered.

But how can we discover just when capitalism has reached a position of dominance? This question is not so easy to answer. One measure, of course, and an important measure, is the value of the instruments used in capitalistic production as contrasted with agriculture. Another measure is the proportion of workers employed in capitalistic enterprises, as contrasted with handicraft and agricultural undertakings. Still another measure is the influence exercised by the possessors of the bulk of the capital goods in the processes of government, domestic and foreign, an influence difficult to assess, but none the less real. Historians could throw some light on it if they would. Systems of suffrage and representative government afford *outward signs*; *secret documents sometimes* unearthed help to reveal the true inwardness of politics.

Judged by such standards early capitalism passed over into high capitalism at different periods in the different nations of western civilization. Approximate dates may be fixed for convenience. For England the year 1846 may be chosen: English capitalism, triumphant in the world market, had no need for a protective tariff, especially on grain consumed by its employees; in that year it smashed the agriculturists in Parliament and forced the adoption of the free trade principle—extended later. In the United States the value of the instrumentalities employed in the capitalistic process overtopped the value of the land about 1850; and in 1865 the armies of the southern planters laid their swords at the feet of northern victors. The Revolution of 1848 in France, which revealed the power of organized labor, likewise revealed the power of capitalism; and the latter triumphed in the struggle, announcing the new day. It will not be forgotten that the Orleanist monarchy established in 1830 was avowedly a

bourgeois monarchy. In Germany capitalism did not get into full swing until after 1870 and its triumph was not politically realized until after the collapse of 1918. In southern and eastern Europe generally, the capitalist process had not advanced beyond its early stage at the opening of the twentieth century—delayed by many factors, including the competition of the countries already far on the way.

IV. An inquiry into the nature of this social giant, equipped with steel and steam, must be prefaced by some reference to its origins, especially as there is a tendency to make it identical with the spectacular appearance of inventions in the eighteenth century and to connect it *intellectually with the Protestant revolt, more narrowly with Calvinism*. Indeed the late Sir William Ashley said that Calvin's letter lending theological sanction to interest (and usury in practise), written in 1545, marks a turning point in the history of European thought. Other writers with less critical discrimination seem inclined to make this the beginning of a capitalist philosophy, inspiring a great upswing in capitalism. Max Weber finds the true "spirit of capitalism" in Benjamin Franklin's *Advice to a Young Tradesman*—a document appropriate to Calvinistic Boston.¹ Indeed, if some thinkers of this persuasion are to be believed, the idea preceded the fact: *capitalism sprang from the soil of Calvinism*: thrift, promptness, industry, honesty the best policy, economic expediency, coupled with interest and profit. Thus the prejudices and passions of religion are associated with the process of attempting to understand the greatest phenomenon of the modern age.

At the other end of the scale are the economists who find the origins of capitalism in sources less mysterious than Calvinism, in primitive accumulations, the gold of the New World, and oceanic commerce opened in the age of discovery. All explanations in this direction are little more than variations on the statement made by Marx in the closing chapters of the first volume of *Capital*. With sweeping dogmatism he crowds everything into a few lines: "The discovery of gold and silver in America, the extirpation, enslavement and entombment

¹ Max Weber, *Gesammelte Aufsätze zur Religionssoziologie*, 3 vols. (Tübingen 1922-23) vol. i, p. 30 *et seq.*; Henri Hauser, *Les débuts du capitalisme*, p. 45 *et seq.* Protestants from capitalist countries, proud of the achievement, accept the allegation as an honor; while Catholic writers, whose religion flourishes best under pre-capitalistic conditions, accept the allegation as a discredit to Protestantism. Science is not concerned with the merits of this controversy.

in mines of the aboriginal population, the beginning of the conquest and looting of the East Indies, the turning of Africa into a warren for the commercial hunting of black-skins signalized the rosy dawn of the era of capitalist production. Those idyllic proceedings are the chief momenta of primitive accumulation. On their heels treads the commercial war of the European nations, with the globe for a theatre . . . Capital comes dripping from head to foot, from every pore, with blood and dirt." Like the Calvinistic explanation, this has the merit of simplicity. When modified or extended in the hands of such writers as Sombart, it still seeks the origins of capitalism in external facts rather than ideas—leaves out of account certain subjective factors without the presence of which no system of bare robbery could permanently flourish.

The truth is that neither simple explanation of capitalism is tenable. Great emphasis can be given to Calvin's teachings on interest only by scholars who are unfamiliar with the doctrines of the scholastics—especially the later writers of that school who sought to apply the principles of Thomas Aquinas to changing circumstances, with a high degree of theoretical and practical success. There was in fact nothing in the dogmas of the mediaeval theologians which would have prevented the rise of capitalism had other conditions of the time been favorable. They did, it is true, forbid usury, that is, to use Dr. O'Brien's definition, "the payment of a price for the use of a sum lent in addition to the repayment of the sum itself." In other words, there was to be no charge for the "use" of money lent. But if the lender suffered any damage by making the loan—found himself in a worse position—then he was entitled to compensation in the form of interest. If the money was not paid back on the day it was due, it was lawful to exact a payment for the delay; and in practise loans were often made payable in a day or two with the understanding that there was to be delay and therefore interest damages for breach of contract. If there was a loss of opportunity to make a profit some other way, the lender could collect interest. If there was any special risk, the lender could exact something in addition to the principal of the loan. It was not unlawful to pay interest as an expression of gratitude for the favor. As business increased during the thirteenth and fourteenth centuries, the scholastics worked hard at interpreting the earlier doctrines, and long before Calvin was born they had established ingenious sanctions

for making capital accumulations and taking what amounts in fact to interest on loans. Calvin's famous letter on interest is important only to those who ignore the scholastics or neglect the evolution of their ideas.

V. When any capitalistic system is analyzed into component parts, it will be found that a certain intellectual climate, as well as technological conditions, is essential to its facile development. Concentrating on the production of goods for profit, capitalism calls for the predominance of secular interests in intellectual life, emphasis on science, business, government, economy, commerce and other related branches of thought. Using the state to maintain order, advance its enterprises in foreign markets and protect its most distant commerce, it requires a freedom of the state from entangling alliances with classes founded on landed possessions—landlords and clergy—a secular state separated from church and justified by secular performances rather than divine sanctions. Resting, at least in its early stages, upon the enterprise and labor of individuals rather than corporations, capitalism needs for its fruition an emphasis on individualism as distinguished from emphasis on the excellence of a settled order of classes such as held the center of the economic field in the Middle Ages. Making use of exact methods, especially as its technical equipment increases, it can live only in an atmosphere of mathematics and calculations, which happen to be at the same time indispensable instruments of the applied science that is so serviceable to capitalism. Buying and selling without respect to person and rank, employing talent wherever it can find that capacity, it thrives on democracy and equalitarian doctrines—the wider spread the better for trade. Finally a wide distribution of knowledge is also necessary for the extensive functioning of capitalism; the directing personnel must read and write; Charlemagne might be illiterate but the humblest factory manager cannot enjoy that luxury; working people must at least be able to read the rules and instructions; and the buying populace must be able to read advertisements if its wants are to be stimulated.

If such intellectual conditions are necessary to capitalist development, it follows that movements in ideas, either as the result of abstract speculation and dialectic processes or as the reflection of novel changes in material circumstances, must be taken into account in explaining the rise and development of capitalism. Now

among the intellectual movements that helped to usher in the capitalist age, the humanism of the Renaissance was the central feature. Although it was connected with the development of mediaeval commerce, it was not a product of that commerce; it was the recovery of a rich pagan learning. Above all it was secular, related to this world, justifying its ways and pleasures. And it must be remembered that humanism was a Catholic, not a Calvinist or even Protestant product: Protestantism hindered rather than promoted its development. Catholics were mistaken, perhaps, when they thought that they could play with Greek fire and yet preserve intact the closed system of Christian theology, but they took the risk nevertheless. Another aspect of Catholic thinking which contributed to the secular interests and individualism of capitalism was the nominalistic philosophy of the schoolmen. This philosophy regarded the world as a concurrence of persons and things and worked as a disintegrating force on the creed of realism with its theory respecting a framework of underlying reality appropriate to a rigid society. Ground between humanism and nominalism, the intellectual heritage of the Middle Ages was in process of disintegration before Calvinism came on the scene.

No doubt Protestantism accelerated this process in many ways. It intensified the old conflict between church and state, aided in the establishment of the supremacy of the state in Protestant countries, and lent countenance to sequestrations of clerical property which helped to decimate the clerical wing of the landlord class. It is true that for a time Protestant states maintained a public religion, but the multiplication of sects made the practise an object of attack and emphasized more and more the secular character of government. Yet we should be on our guard against attributing too much to Protestantism *per se*; for even in Catholic countries conflicts of one kind or another led to the dissolution of the Jesuit order, to sequestrations of clerical property, and finally to the separation of church and state. How far those operations were due to ideas that filtered in from Protestant nations or to the rise of the bourgeois among Catholics is a matter of speculation which historical research has not yet determined. Indeed the extent to which Protestantism was an economic movement is still the subject of animated debate among scholars. Yet when all pertinent facts are assembled and weighed, it will certainly be conceded that Protestantism

facilitated the secularization of the state, relaxed considerably the clerical control so useful to the landed classes, and gave the state a freer rein in creating conditions favorable to capitalism.

By the middle of the nineteenth century the supremacy of the state was firmly assured in all countries of western Europe; such remnants of state-church union as remained had clearly become anomalies to be eliminated in the course of the next few decades. The state was emancipated from scholastic economics, theories of the fixed social order and other doctrines appropriate to a society founded on status as distinguished from contract. The ground was thoroughly cleared for economic action by the state and for an economic philosophy of capitalism that viewed the state as a policeman keeping order for the owners of property.

In other relations Protestantism prepared the way for capitalistic economy. Under its influence the clergy, supported by landed foundations administered by clerical agents, practically disappeared; for the economically independent clergy it substituted a clergy dependent in the main upon voluntary contributions from the members of the congregation. In short the pulpit was subjected to the pew and inevitably took on more or less the thought coloration of the parishioners. At the same time the dictatorship of theology declined and the secular preoccupations of church goers deflected the stream of theological tendency. By the reduction in the number of holidays and festivals Protestantism released more time for productive labor, and by emphasis on salvation by faith rather than works it released more of life for the business of money making and wage working. Laying stress on the direct and immediate relation of the individual to God, it contributed to the individualism in thought and practise which served capitalism in obtaining its necessary supplies of entrepreneurs and wage workers. In praising the virtues of thrift, sobriety, promptness and industry, Protestantism facilitated the growth of a system of economy founded on monetary accumulations and regularity in productive processes. Grass may grow and sheep may graze if the peasant lies drunk under the hedge occasionally, but the wheels of mills cannot turn steadily if boiler stokers must have frequent debauches. A state of affairs calling only for amused comment in one set of circumstances becomes intolerable in another. The Puritanism of Protestantism served the promotion of capitalist enterprise.

Incidentally and apparently without calculation, Protestantism aided the cause of education, so essential to economy founded on exact knowledge. With a view to keeping their children loyal to their particular set of dogmas, the members of each sect early adopted the practise of teaching their offspring the rudiments of learning so that they could read at least the catechism and the creed. Faced by the disintegrating rivalry of Protestantism, the Catholic church adopted a similar practise. But having opened the gateway of learning, they could not set bounds to the outcome. The growing secular preoccupations of the age pressed through the portals of educational institutions. The high cost of sustaining religious schools led to the practise of asking for state assistance for education, and the rivalry of sects, which was increased by this action, contributed steadily to the secularization of educational control and the educational process itself. Where churches insisted on maintaining religious schools they were nevertheless compelled to adopt secular curricula to prepare their children for earning a livelihood in competition with children prepared by the public schools. By the middle of the nineteenth century even the religious schools were supplying boys and girls well enough equipped with secular learning to take part in industrial processes. At the same time the development of printing machinery and the application of power to presses made possible the publication of cheap books and newspapers, feeding secular and practical interest outside of the schoolrooms. Learning and the distribution of knowledge had passed beyond the control of clerical authorities.

Forwarding the same secular and individualistic tendency, the doctrines of natural right and equality, associated with the name of Rousseau, operated powerfully in the capitalistic direction. Defying divine right, advocates of natural right laid emphasis on man as an enjoying, producing and consuming animal, thus lending sanction and rationality to the creation and use of goods. At the same time the individualism affiliated with equality worked against old associations and fixed structures such as guilds and feudal ranks and in favor of freedom of opportunity for entrepreneur and laborer. It was in the name of Rousseau that the vestiges of feudalism were destroyed in France during the revolution, that guilds were abolished, and the way cleared for the bourgeois order of things. If that same equalitarianism made trouble for the bourgeois

later, its service as a stimulus to economic activity cannot be denied. As for natural right, it clothed in a realistic garb the undertakings of capitalistic enterprise which was nothing if not natural—employing the materials and powers of nature in the creation and distribution of goods with a view to earthly rewards.

The development of natural science, which ran parallel with the evolution of natural rights, besides contributing to the technical side of capitalism, also made profound alterations in the intellectual climate, adding features more favorable to that process. Lord Bacon, the father of the movement—to make an arbitrary break in an endless stream of thought—set an example to the coming generations by resorting to experimentation with natural phenomena and glorifying the application of this method to the creation of objects of utility. Bacon's work was advanced by Descartes who helped to break the dominion of authority over reason and made substantial additions to mathematics and physics. Turning from the earth, Newton applied the same mental processes to the starry heavens, discovering one law underlying the structure of the universe. In every department of science the idea of natural law was utilized with fruitful results. Carried into France, the underlying concepts of naturalism were made the basis of an immense intellectual effort, culminating in the *Encyclopédie*, and were employed in the intellectual manipulations that accompanied the triumph of the bourgeois in the revolution. Temporarily checked by reaction, this concept of a material universe subject to natural law flowered again during the opening decades of the nineteenth century, adding philosophic sanction to the production of goods while fertilizing the application of science to the same ends. Hence it may be said that mathematics, the rationalism rooted in its logical processes, analysis of the materials of the world through the aid of chemistry and physics, and belief in the universality of natural law, enriched the climate for the flowering of capitalism—itsself the quintessence of rationality.

VI. While mathematicians, natural philosophers and physicists were at work developing the technology and intellectual climate favorable to capitalism, political events marched in the same direction. The Napoleonic wars dealt death blows to feudalism in Spain, Italy and Germany; Napoleonic decrees abolishing feudalism, sequestering clerical property, suppressing convents and wiping out interna' cus-

toms lines over wide areas of Europe, could not be permanently undone by the most vigorous reaction. In Germany Napoleon not only leveled hundreds of feudal principalities to earth and secularized clerical property; he prepared the way, through partial consolidation, for the unification of Germany, a condition prerequisite to the flowering of capitalism beyond the Rhine. Equally important in the same direction were the collateral consequences of his wars and policies. It was in girding herself for the war of liberation against Napoleon that Prussia, under the leadership of Stein and Hardenberg, abolished serfdom, created a popular army and called into life the ardent nationalism which later supported the Zollverein. Napoleon himself was a titanic rationalizer; his contributions to finance and banking, to the codification and simplification of the laws, to administration by technically competent officials, to military organization and supply, to the development of industries on the continent, to the construction of roads and public works, all marked him out as the child of his time—no divine Alexander or Caesar, as he himself once humorously remarked, but the genius of the age of reason, the forerunner of triumphant capitalism.

If the defeat of Napoleon was marked by a temporary and partial clerical and feudal reaction on the continent, it immensely facilitated the advance of capitalism in England. Through the additions of territory won by arms and confirmed at the settlement of 1815, Great Britain widened her trading empire and extended the markets for her manufactures. Enriched by the profits of twenty-two years of fighting, English capitalists now completely overtowered in wealth and effective power the landed aristocracy already heavily diluted by the infiltrations that had been going on since the seventeenth century. In the Reform Bill of 1832, extending the suffrage to these and other bourgeois, was registered the political outcome of irreducible economic fact. With the decline of the landed aristocracy went a decline in the clerical estate attached to its fortunes. If the universities still controlled by the Church of England clung to the classics and to religion, English thinking outside of the universities swung heavily over to utilitarianism, economy and naturalism; consider Bentham, the two Mills, Ricardo, Lyell, Darwin and Spencer. If the masses remained attached to the church or to the evangelical sects, the prophets of the

new industrial order went in for rationality and skepticism. With her peasantry expropriated from the soil and her landed aristocracy subjected to mill owners and merchants, England passed into the stage of triumphant capitalism before the middle of the century, and thus led the world in that form of economy and in the development of the intellectual patterns and colorations appropriate to it.

On the continent, where temporary reaction restored the appearances of clericalism and feudalism, the forces of economic evolution made headway in spite of all attempts to erect the old barriers anew. Fifteen years after the Bourbons were restored they were finally expelled in the Revolution of 1830, which frankly established a bourgeois monarchy, supported by bankers and rentiers. When the banking aristocracy which sustained Louis Philippe refused to make concessions to the mercantile and manufacturing elements, it was overthrown in the February Revolution of 1848. By its very stubbornness it rendered impossible a smooth transition to simple bourgeois order and brought about a crash which awakened a new estate, the working classes, to political activity, threatening capitalism by a premature communism. Nevertheless, with the aid of the third Napoleon, the communistic danger was averted, the empire was restored, and conditions favorable to business enterprise were established. "Sooner or later war will have to be declared on the Americans," remarked Empress Eugenie to Napoleon III one day in 1853. "War, my love," replied the emperor, making a false prophecy, "is no longer possible in France; we are, so to speak, hemmed in by material interests and trade, which are all in all." To such a point had come the nephew of the great Napoleon who sneered at the English as a race of shopkeepers. The romantic age of the Bourbons had passed forever. France was on the way to the third republic.

In Germany and Italy the consolidation process so swiftly advanced by Napoleon I was completed shortly after the turn of the mid-century. It was in 1834 that the unifying Zollverein was inaugurated; thirty-three years later, in 1867, the North German Confederation was launched, to be completed by the addition of the south German states four years afterward. The theater was being prepared and energies released for a remarkable upswing of capitalism in Germany. It was in 1861 that Victor Emmanuel was crowned king of united Italy and in 1871 that his capital was moved to Rome. In

the meantime the Austro-Hungarian complex of states and peoples was being reorganized on a compromise basis and a vast territory prepared for unhampered trading relations. How far this state-building movement was the result of railways, improved roads and rising industries cannot be determined by economists, but there is no doubt that by enlarging the trading area, eliminating tariff barriers, facilitating the construction of railways for strategic reasons, political unification created economic and legal conditions favorable to the expansion of capitalism as against feudalism.

During these years of consolidation in central and southern Europe, domestic legislation, as well as wars and constitution making, aided the capitalistic process by eliminating various restraints of feudal tenures on the free movement of labor. As already indicated, in 1807, Prussia abolished serfdom by a decree designed to "remove every obstacle that has hitherto prevented the individual from attaining such a degree of prosperity as he is capable of reaching,"—a formula which would have suited Franklin and Calvin. By a law put into effect on July 1, 1848, serfdom was extinguished in Austria, and by an act of September 7, 1848, there was a sweeping abolition of feudal vestiges in that realm, in language which recalled the famous French decree of August 4, 1789. During the same revolutionary year, 1848, the serfs of Hungary and Croatia, under various laws and decrees, obtained "personal liberty." In 1861 Alexander II emancipated the serfs of the Russian Empire, thus carrying the liberation movement to the gates of the Orient. Although the abolition of serfdom destroyed the legal foundations of servitude it did not of course produce the same results everywhere; neither did it always give land to the former tenants or free them from charges in the nature of indemnities. But broadly speaking, it worked a revolution in agricultural economy and, what was more significant, legalized more or less the freedom of migration, national and international, so useful in supplying labor for capitalist enterprise.

Beyond the borders of Europe were occurring events hardly less significant for western civilization: the development and settlement of Australia, the opening of China and Japan to western commerce and intercourse, the penetration of Africa, the independence of Latin America and the exploration of distant islands of the seven seas. Across the Atlantic a new political power was rising on the world horizon:

the United States of America. During this period Louisiana and Florida were purchased, Texas was admitted to the Union, and war was waged with Mexico, ending in annexations that carried the borders of the country to the Pacific; in 1867 Alaska was purchased, with distant islands near the outposts of Japan. This period witnessed the triumph of Jeffersonian and Jacksonian democracy and finally, in 1865, the victory of capitalism and freehold agriculture over the slave planting system. American industries and agriculture furnished an outlet for the overflowing populations of England, Ireland and Germany; and wheat from American fields exerted a more powerful influence on European economy than the gold of the Spanish conquistadors. To the United States European political and social philosophers, such as de Tocqueville and Harriet Martineau, came to find illustrations and confirmations of their European predilections. A republic and a democracy, anticipating by generations the fate of Europe, America was both an inspiration and a menace to contending parties in the Old World. Neither the rage of Carlyle nor the meditation of Sir Henry Sumner Maine could leave the United States out of its sweep.

To add to this account of intellectual movements, political events and economic legislation, a description of the great inventions of the period under consideration would be a work of supererogation. Yet it may not be amiss to call attention to the fact that between 1800 and 1865 steam navigation was established and transoceanic lines opened to all parts of the world, railways were inaugurated and a network of lines spread over western and central Europe, and telegraphic communications began to be employed among all the great centers of commerce. Meanwhile improvements in textile machinery, the steam engine, iron-working equipment, and indeed the whole outfit of manufacturing, poured in such bewildering rapidity from workshops and laboratories that nothing short of an encyclopaedia can give an adequate impression of their number and importance. For our purposes their significance lies especially in the acceleration of the capitalist process as a productive and an accumulative operation, in the creation of capitalists and working classes, in the disintegration of feudalism as an economic and social relation, in the extension of rationalization over increasing areas of human activity, in setting fixed orders of society afloat—in short, revolutionizing the social and intellectual heri-

tage of the Middle Ages from the bottom to the top. Indeed it would be well to remember that during this period Justus von Liebig (1803-73) made his revolutionary applications of chemistry to agriculture, invading a field long dominated by rule of thumb, signs and omens, and bringing to rural methods and mentality the dissolving alchemy of rationality, supplementing the work of Stein in refashioning mankind's oldest work in the image of scientific capitalism.

VII. A transformation in economic and political arrangements so fundamental as that just outlined could not fail to produce novel patterns of thought and to bring about novel applications of inherited patterns. Naturally the center of intellectual interest was moved ever nearer to the new center of actual interest, capitalism and its system; and the conflict of ideas that raged around this realistic social structure and process spread to the uttermost borders of thinking, even into music and aesthetics. In beginning a survey of this intellectual revolution, it is well to recall that none of the participants were disembodied spirits, not even the cold-blooded scientists who so passionately announced their lack of passion. All of the thinkers in this period, as in all other periods, stood in some relation to the feudal order that was crumbling or the capitalistic order in the process of becoming. By family origin they were of feudal, capitalistic, mercantile or mixed ancestry, and in living and earning a living were involved more or less in the one system of economy or the other. Their education leaned either to the clerical and philosophical, on the one side, or to the practical and scientific, on the other. Some of them were, no doubt, more or less detached from their environment, but the detachment was a matter of degree, not of absolutes. If economics boasted of being a science of actuality, it is appropriate to remember that a large body of critics looked upon it as a defense mechanism for capitalism, and Karl Marx turned its leading doctrines to the ends of a communist revolution! When economists declined to answer questions respecting the evolution and outcome of their subject matter, on the ground that such inquiries were irrelevant, they were admitting limitations rather than improving the status of their science.

New conditions in England were especially favorable to the development of what may be called "pure economics," that is, thought about business untinted by clerical and scholastic

aspirations. In that country the feudal aristocracy was practically submerged under capitalism. Advancing far ahead of France and Germany in technology and large scale production, masters of the world market by virtue of their earlier development of machine industry, English capitalists needed no protective tariffs to save them from foreign capitalistic competition. Hence free trade was decidedly to their interest and in promoting it they were not compelled to make terms with the landed aristocracy; on the contrary, they could force free trade upon the country by their own action. Isolated by the sea and defended by the navy, they needed no standing army with its feudalistic heritage and mentality. Rejecting military aid as a defensive force against foreign countries, they could, with more logical consistency, reject it in domestic affairs. For these reasons, therefore, they had to make no serious compromises with feudalism or cameralism, and could go straight to the promotion of capitalism with fewer handicaps of heritage than their brethren on the continent. Practical interests, material circumstances and intellectual climate favored a concentration on "pure economics" as distinguished from "political" economy and an emphasis on the economic man in contrast to the man affiliated with a class order (*Standesordnung*). Thus temporary and local conjunctures gave to English "economics" a validity akin to that of natural science, at least in the minds of its creators and beneficiaries.

Realistic thinking about this order, that is, thinking undisturbed by metaphysical and clerical inquiries, was distinctly favored by the full-flowered development of English materialism. Hobbes, Locke and Hume had made immense contributions to this scheme of world interpretation, and as the eighteenth century turned into the nineteenth, Jeremy Bentham applied it to social phenomena in his *Introduction to the Principles of Morals and Legislation* (published first in 1789 and in a new and corrected edition in 1823). "Nature," he declared, "has placed mankind under the governance of two sovereign masters, pain and pleasure. . . . They govern us in all we do, in all we say, in all we think: every effort we can make to throw off our subjection will serve to demonstrate and confirm it. . . . The community is a fictitious body, composed of the individual persons who are constituting, as it were, its members. The interest of the community then is, what?—the sum of the interests of the several

members who compose it." Out of this theory of utility flowed Bentham's theory of political economy: "The business of government is to promote the happiness of society by punishing and rewarding." In other words, the function of thinking about society and its component individuals is a matter of calculation and balancing, akin in spirit to the bookkeeping operations of the counting house. To such a point had the materialist conception of life brought the speculative technology which the economists of capitalism were to manipulate during the first half of the nineteenth century.

In the field of theory four men—Ricardo, Senior and the two Mills—and in the sphere of practise two men—Cobden and Bright—developed the colorative system of capitalist philosophy into a logical structure of dogma, all within a framework of property conceptions rescued from the ruins of feudalism. Yet it is not easy to portray that structure, for it was composed, in part, of "iron laws" of rent, profit rate and wages, subjected to ruinous limitations and exceptions, and, in part, of moral aspirations quite foreign to the strict business of natural science. Broadly speaking, however, it consisted of the following parts: Society is composed of individuals, each struggling to avoid pain and to secure pleasure-giving goods. Where legal freedom of contract and of motion is allowed, the individual applies his talents and capital to the enterprise for which he is best fitted. Competition guarantees the survival of those who render economical services at the lowest price. Competition and rent regulate prices, profits and wages, so that each productive factor in society obtains a reward fairly apportioned to its deserts. Pressure of population keeps wages near the subsistence level, and the improvidence of the poor assures an abundant labor supply. Everybody is the best judge of what is beneficial to him, and by trusting to his instincts and reason can find the place in society to which he is best adapted. Attempts to control prices and wages are interferences with natural law, ruinous in consequences and bound to fail. The freedom that works so well within the state works equally well among states; under a regime of free trade each nation produces the goods for which it is equipped by nature—climate, soil and resources—and by talent; and a free exchange of goods among states results in the widest benefit to all, each party to the transaction receiving the most desirable goods at the lowest price. If private monopolies arise and control prices they

violate natural law; if trade unions make the same attempt to control wages they also violate natural law. As for the state, its duties are clear: its business is to protect property and to keep order, allowing the economic machine to function freely under its own momentum—the profit-making passion and the struggle for existence. Obviously this is a scholastic-Newtonian scheme of thought, founded on a fixed-order notion of things—not Hegelian and Darwinian, based on the concept of eternal flux. Indeed it was a fashion in the early years of the nineteenth century to refer to Ricardo as "the Newton of political economy."

Yet as a matter of fact, as Paul Rostock points out, Ricardo's iron law of rent rested on mobile factors—the progressive decline in the productivity of land, pressure of population on subsistence and the ruin of capitalists by the recipients of rent. Although Ricardo himself put off the evil day by reference to technology and improvements in agricultural economy, as Rostock continues, that was a subterfuge, not a square facing of his own logic; and had Ricardo been keener he would have been forced to inquire whether the landlords would go back to feudalism or use their rent to build a new capitalism, or whether labor would smash a system which brought ruin to great masses of mankind. If John Stuart Mill built his political economy on the same Newtonian order of thought he nevertheless privately did not believe in the irrefrangibility of his own system, as his autobiography conclusively shows. But by that time the latticework of "iron laws" was hopelessly shattered by criticism, and within a few years the editor of the *Encyclopaedia Britannica*, confessing that the once solid system of political economy was in ruins, omitted the subject entirely, offering in exchange a historical review of the theme which was notable mainly for its tone of melancholy resignation.

Although the Newtonian economics of the English classicists made some headway on the continent, both economic and political conditions rendered impossible such a complete intellectual victory there as occurred in England. It is true that some French and German thinkers took over the whole creed of Manchesterism; it is true that Napoleon III, first and foremost a theorist, who had lived long in England, coquetted with free trade doctrines; but the most influential of continental economists, such as Adam Müller and Friedrich List, worked in the direction of nationalism; and Napoleon III was

vigorously opposed in the French Parliament in his free trade negotiations. The reason is not far to seek. French industrialists demanded protection against the advanced competitors in England. Exigencies of national defense required the construction of railways and other public works with respect to strategy as well as economy. The struggle for unity in Germany and the popular revolt against Napoleonic power gave a national turn to economics that contradicted at many points the cosmopolitan materialism natural enough in English economics. Moreover the survival of feudal monarchies, such as that of Prussia, with their bureaucracies and cameralistic traditions, kept intact many barriers to the free play of bourgeois economic interests. It was by no means accidental, therefore, that List entitled his great work, published in 1841, *The National System of Political Economy*; neither was it due entirely to his long sojourn in the United States; the realities of life in Germany made the order-of-nature economics of the Ricardian school unworkable, if not unthinkable—certainly inappropriate—for a country that was not an island and was still governed by feudal estates.

VIII. From many angles the system of political economy favorable to the development of capitalism was brought under a fire of criticism and confronted by alternative schemes of thought, occasionally in the guise of natural science. Some of these criticisms flowed from the ideology of the feudalism which capitalism was supplanting—the *Standesideal* of the *Standesordnung*, characteristic of the agrarian, handicraft and mercantile economy of the Middle Ages. The vast literature of Catholic reaction which welled up after the storm of the Napoleonic wars comes almost entirely under this head. Only with difficulty could the Catholic church, which flourished best in agricultural countries and had long been supported mainly by landed endowments, bring itself to accept capitalism as a system of production, and never did it reconcile itself with the natural science, skepticism and utilitarianism of that order. One of the fatal mistakes listed in the *Syllabus of Errors*, issued in 1864, was the error that "the Roman pontiff can and ought to reconcile himself to, and agree with, progress, liberalism and civilization, as lately introduced." Idealizing the feudal relation in which superior persons protected and subordinate persons served, Catholic writers attacked the cold-blooded economy which en-

abled an employer to wash his hands entirely of all responsibility to labor, even in times of industrial crises when thousands were on the verge of starvation.

Nor was this type of thinking confined to Catholic writers. In England it was represented by the vehement Protestant-skeptic Thomas Carlyle. When the sources of his inspiration are explored and the types of his illustrations classified, it will be found that he was the philosopher of idealized feudalism. In praising aristocracy and crying down democracy he was celebrating the heritage of feudalism. In his *Past and Present* he contrasted the feudal ideal with the capitalist order around him. His hero Frederick the Great was a war lord who talked about serving his people. When Carlyle assailed capitalists he assailed them for not assuming toward their laborers the obligations of responsibility which a chivalric lord was supposed to have assumed toward his serfs. If he laid stress on natural inequality, it was not to assure Ricardo's capitalist an abundant labor supply but to emphasize the reciprocal duties of employers and employees which he conceived in mediaeval terms. Liberalism, democracy, laissez-faire, utility and the entire intellectual baggage of capitalism Carlyle looked upon as sheer anarchy, destructive to morals and hence impossible as the philosophy of a going society. "A high class without duties to do," he once exclaimed, "is like a tree planted on a precipice from which all the earth has been crumbling." Although he never pictured his reconstructed capitalism in concrete terms, Carlyle's teachings were certainly hostile to political economy as handed down by Ricardo and exerted a powerful influence on English social speculation during the period under consideration.

Carlyle's companion in arms, John Ruskin, combined the *Standesideal* of his friend with a passion for the aesthetics of the Middle Ages. To him also the materialistic teachings of political economy, its indifference to moral as distinguished from market values, were utterly abhorrent; for the liberalism of Gladstone and the conservatism of Disraeli he had only amused contempt; for the feudal ideal of subordination, reciprocal duties, just price and established quality he maintained to the end an unbroken admiration. To give the title "captain" of industry to a modern capitalist who lived well while his army was either miserable or starving from unemployment was to Ruskin scarcely short of sacrilege. If in his search for a remedy

for evils as he saw them he turned to a kind of state socialism, it was not because he had any sympathy with social democracy of the Marxian type; it was because he believed that capitalists themselves would not establish a system of moral reciprocities and that only the government could be induced to create the new social order. In itself that order, as sketched in the preface to *Unto This Last*, was a kind of feudal socialism in an idealized form. Moreover he emphasized in his scheme a phase somewhat neglected by capitalist economists, namely consumption, especially as a moral act. "Wise consumption," he insisted, "is a far more difficult art than wise production." Political economy, he contended, "consists simply in the production, preservation and distribution, at fittest time and place, of useful or pleasurable things." In other words, it is a science of making the natural order conform to mankind's moral and material needs, not a science of a natural order commanding mankind's obedient adaptation. Of Ruskin's great influence there can be no doubt; and in many ways he was more of a prophet—hence more scientific—than Ricardo or Richard Cobden.

With appropriateness and acumen capitalism was attacked in France by the scion of an ancient noble family, Comte de Saint-Simon, who had served in the American Revolutionary War and was proud of calling himself a soldier of George Washington. Although he made a fortune speculating during the French Revolution, Saint-Simon was never affiliated in work or thought with the capitalist process. In spite of his devotion to the idea of progress he clung to feudal concepts of economy and Christian concepts of social ethics; when he issued his comprehensive attack on capitalism and his program of socialism, he entitled it *The New Christianity* (1825). It was from the work of Saint-Simon that his pupil and disciple Comte derived the inspiration and general drift of thought which evolved into the positive philosophy and the grand sociological concepts associated with it.

In the same general class came the Swiss historian and economist Sismondi, who frankly confessed that it was not science but the observation of the distress caused by panics and pauperism—the disharmony of the capitalist system—which led him to attack it and to propose instead a cooperative order of society. Accused of being a conservative romanticist, looking back to the established order of old times, he freely accepted the characterization and made the most

of it. Of noble origin and classical training, he had little sympathy, practical or intellectual, with the materialistic economists, such as Adam Smith and Ricardo. Without attacking machine industry, he proposed to transform it in the image of the inherited moral order. It was as a prophet of this direction that he became an influential contributor to the development of utopian socialism.

Indeed it might be said with justification that the whole philosophy of utopian socialism, to be generalized from the works of Owen, Saint-Simon, Fourier and Sismondi, corresponded with strange exactness to the fixed order of the just price and established quality idealized by the mediaeval economists. None of the utopians accepted the idea of mankind as the helpless victim of economic laws; all of them insisted, on the contrary, on the possibility of creating an ideal moral order out of the materials at hand. If Owen clung to a curious kind of deterministic materialism, he entitled his utopia "the new moral world." If the utopians made use of natural science in their speculations, none of them ever surrendered to the Newtonian concept of an iron-law nature. All of their utopias were small colonies combining agriculture and handicrafts, assuring a minimum subsistence to the participants, production for use rather than for profit, and quality standards such as the old guilds were supposed to maintain. It would be almost safe to contend that the utopian socialism, so vigorously opposed to realistic capitalism, was at bottom a *Standesordnung*, borrowed from the feudal age and adapted to the technology of the early era of capitalism. Perhaps this may help to account for its transitory character and its failure as a practical force in the first half of the nineteenth century. Still it would be a mistake to underestimate its influence on social thought; it was one of the powerful intellectual currents of the age.

Another variant on the contemporary antithesis to capitalism and capitalist economics was Marxian socialism and Marxian economics, which should in truth be separated. Coming after utopian socialism had flowered in many forms and capitalist economy had found its Newton in Ricardo, Marxian economics was a clear fruit of both, nourished no doubt by the revolutionary events of 1848. Although Marx could hardly find words scornful enough to express his opinion of the utopians of every brand, he was familiar with their writings and derived ideas from them, perhaps even the most

utopian idea of all, namely that at the close of the capitalist period would be ushered in the final order of freedom for mankind. His collaborator Engels, who deserves more credit for the labors of the partnership than he has ever received, was not only acquainted with Owen's utopianism, but wrote for Owen's utopian paper, *The New Moral World*. Hence we cannot avoid the conclusion that both Marx and Engels were thoroughly saturated with utopianism—a scheme of thought strangely conforming to principles of scholastic economy. As Otto Rühle says in his *Karl Marx: Leben und Werk* (Dresden 1928; translated by Eden and Cedar Paul, New York 1929), "Paris was, at the time Marx lived there, a great melting pot full of socialistic and revolutionary ideas. There were to be found remnants of Saint-Simonism, ruins of Fourier's phalanx movement developed by Considérant, Christian socialism according to Lamennais, petty-bourgeois socialism in the variations of view represented by Sismondi, Buret, Pecqueur, Leroux, Vidal and others. At the beginning of the forties Etienne Cabet appeared in Paris again, after he had studied in England the utopianism of Sir Thomas More and the practice of Robert Owen" (p. 87 of German text). In the development of their economics, however, Marx and Engels used primarily the writings of Adam Smith, Ricardo, McCulloch and the classical school, and turned "iron laws" and materialism against the very system mirrored in and defended by them.

While making heavy borrowings from classical economics and utopian idealism, Marx and Engels also collected fundamental concepts from history, both written and observed. The idea of the class struggle, which they so extensively exploited, stood out firmly in the writings of Aristotle, Machiavelli, Harrington, Hobbes, Locke and many other social philosophers; and it was well known to thinkers in Europe and the United States, especially to the framers of the American constitution and defenders of it, like Hamilton, Madison and Gouverneur Morris. What they did not discover by study Marx and Engels learned by direct observation. "After the establishment of great industries," wrote Engels in his work on Ludwig Feuerbach, "especially at least after the European peace of 1815, it was no longer a secret to any person in England that the whole political struggle there turned on the quest for power on the part of two classes, the landed aristocracy and the bourgeoisie. In France, with the return of the Bourbons, the

same fact came to consciousness; the historians of the restoration period from Thierry to Guizot, Mignet and Thiers were unanimous in agreeing on it as the key to the understanding of French history since the Middle Ages. And after 1830, in both countries, a third contestant for dominion was recognized, the working class, the proletariat. Relations had so simplified themselves that anyone would have been compelled to close his eyes to escape seeing in these three great classes and the opposition of their interests the driving force of modern history; at all events, in the two most advanced countries." Students of history, Marx and Engels were subdued to a dynamic sense foreign to the Newtonian economics of the bourgeois; observers of contemporary political conflicts, they could not avoid seeing the inevitability of a social struggle even within the framework of a "natural order."

Besides approaching capitalist economy from the historical angle Marx and Engels looked at it through the intellectual structure of German philosophy, especially Hegelianism. As Germany did not shake off feudalism and clericalism with the same thoroughness as "the nation of shopkeepers," so it did not develop until the nineteenth century a school of materialistic thinkers comparable to Hobbes, Locke, Hume and Ricardo. In being more "reactionary," German speculators escaped the facile superficiality of the sensationalist school and combined mediaeval mystification with a profundity of thought not nourished in England. Perhaps, also, the political and armed conflict between France and Germany from 1793 to 1815 contributed not a little to the rejection of the materialism of the Diderot-Holbach direction. At all events German thought during the opening years of the nineteenth century gave a distinctive environment for the consideration of economic, social and historical questions. Marx, brought up on Hegel, could not by any stretch of the imagination see eye to eye with English economists of the natural-order persuasion.

In a passage of striking power Engels expounded the Hegelianism that counted so heavily in the Marxian formulation of political economy: "With Hegel the truth which had to be recognized in philosophy was not a collection of ready dogmatic propositions which, once found, would only have to be learned by heart; the truth lay in the process of cognition itself, in the long historical evolution of knowledge, which rose steadily from lower to higher stages

of cognition without, however, ever arriving, through the discovery of a so-called absolute truth, at the point beyond which it could not go, the point where nothing more was left for it to do except to lay its hands in its lap and stare at the absolute truth now attained. . . . Each stage [in thought] was necessary, therefore—proper for the time and conditions to which it owed its origin; however, it was untenable and unjustifiable with respect to the new and higher conditions, which were gradually evolved out of their own internal structures. . . . So this dialectic philosophy put an end to all ideas of a final, absolute truth and absolute human circumstances corresponding to it. Before it nothing stands as final, absolute, holy. . . . Nothing stands before this philosophy except the unbroken process of becoming and passing, the endless march from the lower to the higher, the mirroring of which in the thinking brain is philosophy itself.”

While it is true that Marx rejected the idea that history is the progressive revelation of the divine idea and boasted that he found Hegel standing on his head and put him on his feet, this intellectual and gymnastic achievement was not as revolutionary, from a philosophic standpoint, as Marx imagined. The Hegelian concept itself was the revolutionary element, a concept equally opposed to the *Standesordnung* of scholastic economists, to the natural order of the Newtonian world imagined by the classical economists of England and, if Marx had been daring enough in his logic to see it, to the positive socialist order to be established after “the death knell of capitalism” was rung. Such was the underlying dynamic of Marxian and Engelsian socialism, which possessed the philosophic validity inherent in Hegelianism, spread beyond the borders of economics into history, ethics and sociology, and when fortified by the Darwinian concept of evolution in the animal kingdom became a powerful intellectual force in the mid-century, both dissolvent and constructive, combining faith in the iron laws of nature with the divine hopefulness of the theologian.

IX. From still another angle, that of anarchy, capitalist economy was attacked, Proudhon, the poverty stricken son of a French cooper, taking the lead. Yet in many ways it was merely the extension of Manchesterism to a logical conclusion; the state should not even protect property and life; it should be abolished, and the free operation of natural forces, limited

perhaps by voluntary artificialities, would create the ideal order of things. Proudhon even went so far as to declare that domestic questions could be solved by a bureau of statistics, and that international questions could likewise be resolved by a bureau of international statistics. While there were elements of social control in his scheme, anarchy, the abolition of political dominion of man over man, was the goal which he set before him and the end toward which he thought society was moving.

More violent in temper and methods, still more clear-cut in his anarchist goal, was the Russian agitator Bakunin, who appeared on the revolutionary scene of western Europe during the upheaval of 1848. In his own words Bakunin summed up his attitude to classical economy and Marxism: “Marx is an authoritarian and centralizing communist. He wishes what we wish: the complete triumph of economic and social equality, however, within the state and through the power of the state, through the dictatorship of a very strong and, so to speak, despotic provisional government, that is, by the negation of liberty. His economic ideal is the state as the sole owner of land and capital, tilling the soil by means of agricultural associations, under the management of its engineers, and directing through the agency of capital all industrial and commercial associations.

“We demand the same triumph of economic and social equality through the abolition of the state and everything called juridical right, which is according to our view the permanent negation of human right. We wish the reconstruction of society and the establishment of the unity of mankind not from above downward through authority, through socialistic officials, engineers and public technicians, but from below upward through the voluntary federation of labor associations of all kinds emancipated entirely from the yoke of the state.” Illuminating this creed by more technical knowledge, Bakunin’s compatriot Kropotkin forecast an anarchistic society combining fields, factories and workshops in a single system of communal economy, decentralized and federated, employing no engines of state in direction and control.

An analysis of this system of thought shows that it unites in itself the natural order of the English economists carried to a logical extreme, the equalitarianism of the Rousseau school, and the hatred of the state common to despotic countries where the state was personified in an absolute ruler. From an economic and techno-

logical point of view it was pre-capitalist; that is, it rejected with the scholastics profit making as the prime mover of economic activities, and the society forecast by it was a simple combination of agriculture and petty workshops. When Russians visualized it they usually saw the Czar and the landed nobility swept away and the villages and handicrafts left intact as they had existed for centuries. It was built upon a localized primitive economy, not on a national order, to say nothing of international finance and exchange. Yet it agreed with classical economy in its faith in the excellent outcome of self-directed economic activities undisturbed by state interference. Perhaps its vogue and influence were due to its services to capitalistic opposition to state intervention rather than to the intrinsic power of its appeal as a system of thought.

A fifth attack on capitalistic economics came from the direction of nationalism tinged with socialistic ideas. Practically the work of bringing about political unity in Germany and Italy was entrusted by destiny to leaders of feudal affiliations; in Germany the Prussian state, in Italy the Sardinian state, took the leadership; in both countries the bourgeois, while desiring unity, hoped to effect it by constitutions rather than the sword and were, therefore, more or less in opposition to the actual process of national unification. Bismarck's troubles were with the bourgeois, not the Prussian landlords. In his conflict with the middle classes he even flirted with the fourth estate and cooperated with Lassalle in the formulation of policies. Springing from a landed family, serving the Prussian state, constantly struggling against the restraints of mercantile liberalism, Bismarck could not possibly adjust his mentality to the economics of Manchesterism. The use of the state for economic ends had been a historic practise in Prussia; Bismarck continued it. While socialism was a rising power, he helped to direct it against the bourgeois; after it grew into a menace he made concessions by furnishing instalments of state socialism. When Schmoller became a professor of political economy at Halle in 1864 and Wagner took up his duties at Berlin six years later, state socialism was already in the air, making German economic thinking well-nigh impervious to the reasoning of the Manchester school. That which seemed perfectly "natural" to Cobden did not seem "natural" at all to Lassalle, Bismarck, Wagner and Schmoller, and for reasons "natural" to both situations.

X. Passing outward from economics to the wider implications gathered under the head of sociology, we encounter the same operating forces of circumstantial reality and the same intellectual climate as the conditioning environment. Indeed it is difficult to distinguish sociology from economics on the one hand and from socialism on the other. Comte, who may well be called the founder of the discipline, was a disciple of Saint-Simon, the French utopian socialist; and yet he was at the same time a student of the natural sciences and the naturalistic philosophy which had furnished nutriment for classical economics. His concept of the three stages of social evolution—theological, metaphysical and positive—reflected with striking precision the scientific assurance of his period; and the outcome of his sociology, an ideal society tinged with religion, was appropriate to a thinker early trained in the utopianism of Saint-Simon. Yet by escaping the iron laws of Newtonian economics Comte came more nearly to forecasting the trend of social thought and practise than did his contemporary Herbert Spencer. By emphasizing the contention that neither economic nor political reorganization would alone lead to the goal indicated by social evolution, and by laying stress on intellectual readjustment and universal education, he helped to rescue both politics and economics from the sterility of mathematical inevitability so attractive to the classical economists and the Marxians. More than that; in spite of his vagaries, he widened the periphery of thinking about human society, gave a certain social wholeness to speculation about it, and, by pointing out the synthetic character of modern civilization, helped to prevent an overemphasis of ideas or facts.

It was the breadth of view which characterized Comte, no less than his vagaries, that led the English rival Herbert Spencer to declare that his chief debt to the French sociologist was negative. Spencer's resistance to Comtism was the opposition of a practical and confirmed exponent of Manchesterism, classical economy and materialistic science. In explaining "how little influence Comte's teachings have had on scientific thinking in England," Spencer said with a certain air of hauteur: "Those whose education has been mainly literary are unable to realize the mental attitude of those whose education has been mainly scientific—especially where the scientific education has been joined to scientific tendencies and a life of practical

science continually illustrating theoretic science, as in my own case." In this single sentence Spencer revealed his strength and weakness. Here is the strength of Cartesian mathematics, Newtonian physics, Ricardian economics and Darwinian materialism; here is the weakness of a mind which imagines that the kaleidoscopic motions and emotions of life can be covered by statements akin to chemical formulae in exactness. It was in this spirit that Spencer, a child of the utilitarian age, applied, after a fashion at least, what purported to be rigid canons of thought to the origins of religion, to the rise and development of ceremonials, to social, military and industrial institutions, and to current political practise. The range of his influence was proportioned to the dominance in various countries of the modes of life and thought which he represented; and his work ran the full gamut of scientific expressionism throughout the world. Even if it had not been given the powerful aid of Darwinism its pressure in the currents of thinking would have been immense.

XI. Through the historical writing, no less than through the economics and sociology of the period, rang repercussions of the great political and economic struggles of the age, making necessary many adjustments in the heritage received from the preceding epoch. In the pages of the English historian Macaulay could be traced the long conflict between the capitalistic and landed classes in England and the evolution of their associated ideologies. The passing of the military caste in the island kingdom and the rapid advance of parliamentary government favored the cultivation of research in political institutions, which finally flowered in 1873 in the publication of the first volume of Stubbs' *Constitutional History of England*, the progenitor of a long series of institutional studies. Although the general outlook was widened by Buckle, whose *History of Civilization in England* (published in 1857) aroused a sensation in two hemispheres, it was found on examination that his structure of thought had been reared on economic Manchesterism and the hypothesis of materialism, and reflected current political and theological controversies. Across the Atlantic, in the United States, the Democrats found their historical oracle in George Bancroft (trained in Germany), who united some of Hegel's dynamics with the optimism of Jacksonian democracy; while at the same time the past was recon-

structed for the Whigs by Hildreth, a scholar brought up in the federalist school. In France the historical works of Thiers, Guizot, Thierry, Mignet, Lamartine and de Tocqueville bore deep traces of the controversies which had shaken France since 1789, the new social ideas which stirred Paris to a socialist revolt in 1848, and the contests which the respective authors witnessed. Indeed most of the French historians were statesmen or politicians and mingled the emotions of the forum with the ratiocinations of the study. Their great theme was the justification or condemnation of the upheaval of 1789 with corresponding pertinence to contemporary issues.

If German historical scholarship appeared to be more thorough and more profound it by no means escaped the impacts of the day. In the dark hour of humiliation at the hands of the first Bonaparte, German nationalism, personified best perhaps in Fichte, girded itself as a young giant, making use of universities and all disciplines of thought to strengthen the state for liberation and to inspire the masses with confidence in their native powers. As Cunow says of von Maurer, this school of thought sought in the German past for the secret of a better future; here is the root of the Teutonic theory of racial genius which dominated so much of German thinking of the nineteenth century and passed swiftly into England (a partner of Prussia in the destruction of the Latin Napoleon) where it exfoliated richly in the works of Palgrave, Kemble, Freeman, Stubbs and Green; and then leaped the Atlantic to Johns Hopkins University where it made a powerful impression on a generation of American historical scholars between 1876 and 1900. Besides developing inquiries into Teutonic origins, the German historians of the period, taking note of the struggle for parliamentary government raging on every hand, also laid great emphasis on institutions; hence the monuments of erudition erected by Waitz, von Maurer, Brunner and Gneist, which were so assiduously studied across the channel by English contemporaries. Although Ranke announced a new ideal when he declared it to be the business of the historian to see things as they actually had been, his underlying philosophy was more akin to the faith of Martin Luther than to the materialism of the French and English philosophers (Friedrich Meinecke, *Die Idee der Staatsräson in der neueren Geschichte*, Munich and Berlin 1924, p. 471). After Hegel struggled through the phenomenology of the spirit and the

philosophy of history he came out with an apotheosis of the Prussian monarchy!

From a strictly scientific point of view the most important achievement of the period was the beginning, in various countries, of great collections of documentary and source materials and the foundation of scholarly journals for the publication of minute researches, thus undermining in detail the huge structures erected by the generalizers of the epoch. But it could scarcely be said that this new documentation exercised much influence on the histories of the period done in the grand manner—the histories that made the deepest impression on social speculation and practise. “Scientific history,” claiming a kind of disembodied emancipation from temporal affairs and general ideas, belonged to the future; thousands of doctoral dissertations and specialized studies were to prepare the way for its short-lived triumph near the close of the century.

XII. With respect to the political theory of the period under consideration, the four points of the compass were: the individualistic anarchy of Bakunin and the socialist dictatorship of Marx, the capitalist-constable state of English Manchesterism and the feudal-police state of Prussianism. All other schemes and themes were but variations from these four types of opinion. Whoever starts on a journey through the tangle of political speculation must take his guidance from these fixed points of observation. It matters not whether it is the theory of Fichte, Ranke, Schelling, Hegel and Treitschke, heavily laden with learning and philosophy, or the laborious periods of Karl Marx fusing German ideology and English capitalistic experience, or the dogmatic assertions of Bakunin, or the reasoning of Herbert Spencer’s *Social Statics*; the animus is there and the Q.E.D. of the syllogism is implicit in the assumptions of the first assertion. The political thinking of the age mirrored its realities, with their varied gradations and circumstances. Having long served as a shield of defense for a prevailing order or a foil of attack upon some dominant arrangement in politics, political theory did not emancipate itself from its heritage. If there could be a science of politics akin to the science of physics, no philosopher of this period discovered it.

Perhaps the nature of what passed for “scientific reasoning” respecting the state during the epoch can best be illustrated by the following propositions advanced by Spencer: “Every-

thing in nature has its laws. . . . As with man physically, so with man spiritually. . . . Mind has its laws as well as matter. . . . As with man individually, so with man socially. Society as certainly has its governing principles as man has. . . . Analogy shows us that they must exist. . . . The laws of society are of such a character that natural evils will rectify themselves by virtue of a self-adjusting principle. There follows the inference that it is needful only to maintain order—that the function of government is simply to defend the natural rights of men—to protect person and property—to prevent the aggressions of the powerful upon the weak—in a word, to administer justice.”

Far less tenuous in its thinking was the school of historical jurisprudence founded by Savigny and his generation of German jurists. Two special features of their field saved them from the vagaries that plagued speculation in politics. The first was the logical and almost artistic perfection of the Roman law which they made the object of such profound and affectionate study. Compare, for example, the *Corpus juris* exploited by Savigny with Machiavelli’s *Prince* so assiduously cultivated by Hegel and Fichte! The second was the practical requirements of their profession which held the lawyers nearer to the business of living and working. The first half of the nineteenth century was a period when the old confused laws of feudal relations were being transformed to meet the exigencies of modern economy and codified for the convenience of legislators and practitioners. Echoes of the Code Napoléon reverberated through Germany and Austria to Budapest and Belgrade on the far banks of the Danube. It should not be forgotten that Savigny, besides being a professor in the University of Berlin, was also a politician, a Prussian official from time to time, and above all minister for the revision of legislation from 1842 to 1848. Doubtless experience as a public official or legal draftsman would have altered the angular political theories of Fichte, Marx, Bakunin and Herbert Spencer, bringing them more near to the inevitable course of things. Historical jurisprudence was a powerful corrective to loose political speculation, a useful guide to exact thinking about social relations capable of legal definition, a check on facile hopes and, equally, on facile aspirations for a return upon the past.

XIII. Strangely involved with all the events and disciplines reviewed above was the doctrine

of evolution associated with the name of Darwin, including all its implications for anthropology, psychology and social science. "Involved" is the just word, for besides exerting a profound influence on all departments of thought, Darwinism was a product of this age—the age of early capitalism, materialism and sharp social conflicts. In fact, Darwin himself confessed that while he owed much to his observation of the struggle for existence in the animal world, the idea of natural selection came to him after reading Malthus. In a letter to Haeckel Darwin wrote: "Having attended to the habits of animals and their relations to the surrounding conditions, I was able to realize the severe struggle for existence to which all organisms are subjected. . . . With my mind thus prepared I fortunately happened to read Malthus' *Essay on Population*; and the idea of natural selection through the struggle for existence at once occurred to me." And what was the essay by Malthus? A cold, scientific study originating in the passionless pursuit of truth? On the contrary, it originated as a political and social tract to combat the "dangerous" social doctrines of Godwin. Thus inspired in part at least by a class controversy appropriate to the age, Darwinism naturally lent sanction to the tooth-and-claw struggle of Manchesterism, to the individualistic gospel of early capitalism.

At the same time Darwinism was the logical outcome of a line of scientific research and thinking which ran far back into the eighteenth century, to say nothing of Greek and Roman concepts of biological development. It was foreshadowed in the work of Buffon, Erasmus Darwin and Lamarck. It was worked out to some extent independently by Alfred Russel Wallace. Its advance was promoted by the geological investigations of Hutton and Lyell, the botanical studies of Linnaeus and the innumerable researches of specialists in Europe and America, not overlooking the debt to Asa Gray of Harvard, so generously acknowledged by Darwin himself. All the thinking of the age respecting plant and animal life was subject to the pressures of contemporary natural science and finally eventuated in the *Origin of Species* published in 1859. Inevitably this feverish scientific research forced its way into speculations respecting the origin, development and destiny of mankind. All those who thought widely in that period were profoundly affected by the influences which produced the doctrine of natural selection and survival of the fittest.

Darwin's second great work, *The Descent of Man*, although it did not appear until 1871, was likewise a product of this age, especially of anthropology as developed by the inveterate German traveler and student Bastian, his Marburg compatriot Theodor Waitz, Haeckel at Jena, Canestrini and Barrago in Italy, Lubbock, Tylor, Spencer and McLennan in England. And this anthropology itself was in no small measure the fruit of the commercial and exploring age, of innumerable voyages opening up the most distant and backward places to travelers and observers, of continuous traffic and intercourse between Europe and all quarters of the globe. By swift clippers and later by steam vessels, merchants, naturalists and curiosity seekers, as well as preachers and priests, sailed for all known parts of the earth; secular observers supplemented the reports and interpretations of missionaries, breaking down the limited, parochial views of western Europe and bringing to bear upon social thought a wide knowledge derived from the study of human societies in all stages of development. Like a gust of fresh air anthropology swept through the social speculation of Europe burdened by thirty centuries of limited and traditional theorizing concerning the nature of man and human society, thrusting new ideas into the European heritage and into the rationalizing processes of a period beset by social conflict. Though thrown for a time into violent collision with theology, the new science of anthropology made steady headway as the most emancipating discipline of the epoch. World travel, world geography, world geology and world anthropology were doing more to reveal the nature of man to himself than all the fine-spun speculation that had been accumulated by the opening of the nineteenth century.

XIV. If from departments of knowledge, which are after all highly fictional divisions, we turn to the great ideas of the period which penetrated all branches of thought, we find that they may be conveniently summarized as follows:

State ideology, developed around the Prussian monarchy, especially by Fichte and Hegel, in a time of national uprising against Napoleonic domination and advancing to the state socialism of Bismarck, Lassalle, Wagner and Schmoller.

Nationalism, promoted particularly by the struggle for unity in Germany and Italy.

Anarchy, or the negation of the state, in the decidedly limited form of Manchesterism and the logical and violent form of Bakuninism.

Proletarian socialism, erected into a system by Marx and Engels, and projected on the political stage with the founding of the first International in 1864.

Evolution, from the universal flux of Hegelianism to the systematic naturalism of Darwin, working widely in all departments of thought.

Materialism, with antecedents running back to the Greeks, especially promoted by the philosophers of the eighteenth century and the natural scientists of the nineteenth century, reaching pontifical assurance in the work of Büchner.

Christian ideology, the ethics of the fixed

order, with the scholastic theory of just price and just wages as its essential economic creed.

The idea of progress, launched by Abbé de Saint-Pierre early in the eighteenth century, exploited by Saint-Simon in a socialist direction, by Spencer in the individualist direction, and taking its place finally as a kind of Providence in skeptical circles.

Out of such ideologies, composed of many strands and formulated with varied illustrations, was woven the social thought of the first half of the nineteenth century, a part of the heritage with which all must work in our day.

CHARLES A. BEARD

X

Nationalism

The great changes in social and political thinking during the generation following upon the last years of the sixties remind one of a famous passage in that standard source of the history and psychology of liberalism, the *Autobiography* of John Stuart Mill. The author relates (ch. v) how, through an involved and painful process just after the completion of his twentieth year, he became aware of all the cruel one-sidedness of that extraordinary and precocious education bestowed on him by his father, and how it dawned on him "that the imaginative emotion which an idea, when vividly conceived, excites in us, is not an illusion but a fact, as real as any of the other qualities of objects; and far from implying anything erroneous and delusive in our mental appreciation of the object, is quite consistent with the most accurate knowledge and most perfect practical recognition of all its physical and intellectual laws and relations."

What happened so early in one man's short lifetime, it took the mass of liberally educated European and American thinkers several generations to discover. For a while the ideas of French materialism and English utilitarianism seemed about to flood all civilized mankind with the standardized harvest of their social and political convictions and habits. But precisely at this time the tide began to turn slowly, yet steadily, and ideas and conceptions that appeared to be "illusions," dead and gone, began unexpectedly to make themselves felt as "facts."

If one tried to find a broad preliminary formula indicating the chief lines along which this change affected the social sciences, one might say that the simpler and more vulgarized the liberal doctrine of government and society became, the more it was in danger of being overcome on both its wings by two forces that had been its dangerous critics almost from the outset. One of these was the "organic" conception of social growth first strongly voiced by Burke and the teachers of the Restoration. The other was the "socialist" interpretation introduced by the great English and French pioneers in this field. It is surely not without significance

that the political development of the leading capitalist countries was marked, during this period, by constitutional readjustments of a closely parallel nature. In 1867 Disraeli's second election reform enfranchised the great mass of the urban working classes on whose support "Tory democracy" relied against liberalism. The same year Bismarck, on the advice of Ferdinand Lassalle, made an even bolder stroke in the same direction by incorporating in the new constitution of the North German Federation the same demand for complete universal suffrage that had been made during the Revolution of 1848. Finally what else is the meaning of the reconstruction period in America's history but a similar alliance of Republican conservatism, and even imperialism, with an overwhelming majority of the toiling masses who had been, a generation before, the main support of Jacksonian democracy? It is true that in America and still more in Europe, where socialism started directly organizing its own parties, the conservative-socialist alliance could only be either a passing event or a recurring ideal. But as such it had immense influence in weakening and modifying the hold of liberalism on the modern world.

One of the first prominent results of this influence was the rise of a new nationalism. From the point of view of revolutionary France and of English liberal world politics, national aspirations had been valuable only in so far as they tended to promote the growth of democratic government throughout the world or, to put it in terms of realistic political sociology, in so far as they furnished natural supports for the French and English governments of the period. And, correspondingly, it was found that in German and Italian movements toward national union the cosmopolitan leadership of the bourgeoisie and the intelligentsia far outweighed the influence of more radical and nationalist forces that came to the fore only in times of revolution and of war, and were dismissed again after successes as well as after failures. In contrast to all this, the epoch of the sixties is characterized, on the one side, by the definite victory of the

young German and Italian national governments, accomplished more or less directly at the expense of the last French monarchy; and, on the other side, by the menace of the Russian Empire and of the new eastern nationalism that raised a multitude of disruptive forces in the shape of "nationalities" in the Austro-Hungarian monarchy. The effect of the Franco-German War was not only to complete the eclipse of France and Austria-Hungary but also to complete the union of Italy and to abolish the limitations of Russia's naval power in the Black Sea, thus enabling her to unloose immediately the nationalist forces of the Balkans against the Turkish Empire. The new nationalism was not confined to the continent of Europe. In the England of Disraeli it took the form of that imperialism which not only gave India the imperial name and occupied Egypt but definitely halted the "Little England" spirit in favor of a creative development of the dominions based on self-government and a new consciousness of British racial community.

Second in order of time, though hardly of importance, were the economic implications of the new nationalism which have made the historians call the close of the century the neomercantilist age. In a very significant way the fundamental policies intended to inaugurate an age of shrinking tariff frontiers and of ever widening free trade, produced results exactly the opposite of those intended. The great "most favored nation" treaties between France and England (1860) and between France and the German Zollverein (1862) were equally unsuccessful, the first provoking the economic discontent that brought about the overthrow of the Second Empire, the second showing by the consequent ejection of Austria from the Zollverein the double edged workings of free trade inside and outside the areas of commercial treaties and customs unions. With but slight variations, such as the Morrison tariff in the United States and the Caprivian era of commercial treaties in Germany, the spirit of the period thus grew strongly and increasingly protectionist. There were other developments in the economic history of the time, such as Germany's social insurance, Russia's state railways and France's colonization activities, which recalled the economic leadership of governments in the mercantilistic states of the sixteenth, seventeenth and eighteenth centuries. Even in England the last great remnant of mercantilism had scarcely disappeared with the dissolution of the East

India Company (1857) when the new imperialism unconsciously went back to the Elizabethan models of state monopolized organizations of foreign trade in the creation of the big chartered companies of Cecil Rhodes and his African rivals.

All this was to prepare the way for startling transformations. The capitalistic economy which had so triumphantly spread with the destruction of the older mercantilism and the advent of the free competitive market in commerce, industry and agriculture was on the verge of reaching that new and different stage which has been described as the "high capitalism" of the twentieth century. A new and unheard of development of machine production, financial organization and marketing technique began to evoke new and unheard of economic forces, mostly in new places. An age of steel, instead of iron, dawned after the experiments of Bessemer, Kelly and Holley in America, and of Thomas, Gilchrist, William Siemens and Martin in England. In the later years of the period the perfection of the basic process shifted the center of European steel production from England to the German furnaces fed with the phosphoric ore of the newly acquired province of Lorraine. In precisely the same manner the new era of electricity was born and fostered in the laboratories of Werner Siemens and Emil Rathenau, and the analytical chemistry of coal was inaugurated by the scientific exploits of German universities and technical high schools. Lastly the growing volume of business was taking production and marketing out of the range of the individual entrepreneur, who had been the dominant figure of the competitive economy, and was leading it on to new forms of organization essentially monopolistic in character but as varied in appearance as German government-protected syndicates and American trusts struggling, successfully indeed, with a theoretically free-trade judiciary and legislation.

This tremendous expansion of productive powers was possible only in connection with the new movements of population. One who wishes to understand more than superficially the socialistic side of the neomercantilist epoch must keep his eye on the adjustments that took place in population. The nationalist fermentation of Italy and eastern Europe furnished the United States with the "new immigration" needed to supply its expanding business with cheap and docile masses of raw labor. The same effect was produced in Germany by an extensive process of

internal migration from the agricultural north-east to the centers of industrial production in the west, drawing in its wake a corresponding immigration, temporary or permanent, of still cheaper agricultural labor from Russia and Austria. Karl Marx and Friedrich Engels were not mistaken in applying the experience they had had of earlier English capitalism and the lessons they had learned from English trade-unionism to the new economic and political situation of their native country. In America radicalism took the form of agrarian movements like the free-soil and free-silver agitations.

Now when we remember that the social sciences represent the self-consciousness of society, and that political economy is the oldest and most developed among them, it is not surprising that we should find the structural changes of the society of the epoch most exactly mirrored in the new and very decisive turn taken by economic thought. After the disintegration of Ricardian teaching, brought about quite as much through popularization as through heterodoxy, the time was ripe for a reconsideration of that great body of doctrine called the "classical economics"; and in the sixties English, Austrians and Germans were busy laying the foundations of two huge new wings to be added to the old building on each flank; namely marginal economics on the one side, and the historical school on the other.

It is possible to interpret marginal economics as a reaction against the deadlock to which the classical theory of cost value had been brought by Karl Marx's powerful exposition of labor costs and the surplus of exploitation. Indeed one of the three founders of modern marginalism, Marie Esprit Léon Walras, was through his own father a direct heir to the typical kind of mathematical price theory which the French bourgeoisie had tried to set up in defense against the socialism of Proudhon. But surely if there had never been any French or German socialists, classical economics would still have reached a stage where it would have been in urgent need of restatement. That stage was marked by the passing of the limited period which, in the words of John Maurice Clark, "began with the breakdown of the mediaeval guild restrictions and ended with the growth of industries using large fixed capital." It was only during this period that economists could have been satisfied with the simple concept of value and price as being directly determined by elementary factors employed in the production of commodities. With

the advent of "large fixed capital" production, economic analysis had to fall back upon an earlier and more general, if less simple, aspect of the market, where the ever changing equilibriums of supply and demand would end in the apparently contradictory phenomenon of costs determined by prices. In fact the simultaneous inquiries which in the early seventies reconquered from oblivion the eighteenth century device of marginal analysis as an application of the differential calculus to economic reasoning, were only historically different approaches converging upon this goal of a new "subjective" theory of value and prices. William Stanley Jevons stands, as it were, in the middle, continuing, despite all his opposition to Ricardo, the old utilitarian tradition of the classical school, and so paving a way to the ultimate reconciliation reached by Alfred Marshall and F. Y. Edgeworth early in the nineties. On one side of Jevons, Walras, with the mathematician's aloofness from both realistic and psychological treatment, exerted a sobering influence which resulted in a *risorgimento* of Italian economics rather than in any more marked effect on France herself. On the other side, Karl Menger bequeathed to the Austrian school, of which he was the founder, that subtle but unmathematical psychology which in his country was a heritage of the best of Catholic scholasticism. There also were remarkable crossings and blendings among the three national streams, such as Auspitz' and Lieben's mathematical theory of prices, or Fisher's *Mathematical Investigations in the Theory of Value and Prices*. Correspondingly strong differences inside the national schools came to the fore. In Austria, for instance, the new method was used to attack the more complicated social problems of distribution, so that Menger's school after 1884 was more or less openly split into the more radical group committed to Eugen von Böhm-Bawerk's time theory of interest and the more conservative group inspired by Friedrich Wieser's conceptions of social productivity. Finally in Sweden Knut Wicksell prepared the return to an "objectivism" later perfected by Gustav Cassel, while American economics succeeded in keeping a rather independent position in which the English inheritance was tempered by the early influx of Austrian teaching chiefly by way of Smart's translation of Böhm-Bawerk's volumes on interest. But John Bates Clark's *Distribution of Wealth*, the outstanding work of the close of the century, evoked in support of its marginal pro-

ductivity theory the memory of the great German pioneer of the doctrine, Johann Heinrich von Thünen. After the model of the Verein für Sozialpolitik, founded in 1872, the American Economic Association tried, as in Edwin R. A. Seligman's early work on the theory of taxation, or F. W. Taussig's on the tariff, to connect theoretical economics with economic policy. On the whole America was the only country outside of Germany to do justice by the second most important movement of modern political economy, the German historical school.

It has been the fashion for some time to draw a rather sharp line between what used to be called the older and the younger historical schools of German economists. The former has been identified with the names of Roscher, Hildebrand and Knies; the latter, with the name of Schmoller; and the line of distinction has usually implied a "value judgment" of some sort on the superiority of the former as compared with the latter. Now there is indeed much to separate those older writers from later historical teachers and economists. Although on the surface they seemed as hostile to English classicism as the German university "cameralists" had been ever since Adam Smith's time, they had really a great deal in common with their English post-Ricardian contemporaries, being genuine philosophical liberals with a fairly marked theoretical interest. This is precisely the reason why the historical school did not exert its main force until this generation had passed and the group led by Schmoller took its place. In spite of the famous "battle of methods" between him and the Austrians in the eighties, Schmoller's service to economics in the new German Reich was more closely akin to the new departure of Menger's subjectivism than one might expect. It was another part of the great reaction that had set in against the one-sidedly deductive methods of orthodox utilitarianism and that had been philosophically led on in England itself by the inductive logic of John Stuart Mill. In fact there is the same craving for realism, after an age of self-satisfied "pure" reasoning, in the opening pages of Menger's *Principles* as there is in Schmoller's contemporaneous work on the small crafts in Germany; and their difference, if momentous, is less in the ulterior aim of economic research than in the theoretically rather careless belief in factual inquiry that made Schmoller and the other founders of the Verein für Sozialpolitik disinclined to wait with Austrian patience for

theoretical solutions of the social problems of the new Germany. That Schmoller was as little of a government economist as his Austrian colleagues, who in many cases served their government even in official cabinet positions, is proved in part by his campaign against the social aloofness of Treitschke, the official historian of Prussianism. His position is even more clearly indicated by the fact that both he and his associates in what their opponents called *Kathedersocialismus* were deeply influenced by the constructive side of the spirit of the great German socialists. Instead of viewing the historical school, as is too often done, exclusively in the light of Schmoller's latest period—the period of extensively organized research in the process of Prussian history that really belongs to the succeeding century—one ought to think not only of Schmoller in his entirety but of the whole breadth and depth of the work done in a spirit of friendly rivalry, and not seldom of opposition too, by the other masters of "historical" economics in Berlin, Munich, Strasbourg and Halle. There was Adolph Wagner, most theoretical and (scarcely by coincidence) most radical of all, who in the wake of Karl Rodbertus sustained social criticism on the basis of the Ricardian theory of rent. There was Lujo Brentano, convinced free trader, who yet gave the English the first theory of their trade unions. There was Georg Knapp, historian of agricultural emancipation, whose state theory of money comprised a century's experience of managed currencies. And, lastly, there was Johannes Conrad, whose eminence as a teacher has left a considerable impress even upon many non-German countries, especially America, where he sent Patten to revive the protectionist ideas of Carey. On the whole, although the training of most of the older American economists in the German historical school may have actually had only a slight influence upon them, and the thought of men like Emile de Laveleye, Charles Gide and Emile Levasseur in Belgium and France was at that time certainly much more akin to the German than to the American spirit, there is probably no escape from Schumpeter's conclusion that the deepest meaning of the German effort has nowhere been better resumed and perfected than in the empiricism of the American institutionalists of our day.

It must not be forgotten that since the days of the physiocrats and of Adam Smith there had been a tendency to regard the other social sciences as an outer group circling about the

specialized and segregated science of political economy. Compared with what their state had been in the eighteenth century, their growth had been rather retarded by the concentration of public attention on their "dismal" sister. And not until the latter, with the increasing want of historical and realistic treatment, was again reminded of her more general social backgrounds, could there be sufficient interest created in the progress of the sister branches that were to clear up those backgrounds. Naturally the triumphant development of economics forced itself for a long time upon these other branches as a model of "exact" science. They had only to go one step further back to find the model of the natural sciences that had been so suggestive to economics itself. Thus, while much of the economic work of the period was in rebellion against the older types of the mechanical concept of society, this concept was far from having lost its influence over the rest of the social sciences, and some of the best work done by them could never have been achieved except with the help of naturalists and naturalist thinking.

This is of course especially true of those aspects of social life which are conditioned by the more or less pure physiological data of human nature and its surroundings. These data had from the eighteenth century onwards been viewed preeminently in the light of the individual *homme machine*. With the advance of socialism their significance came to be regarded more and more from points of view that transcended the individual and that were represented mainly by the two great biological doctrines of evolution and of the social community. As to the first, Darwin's mechanical theory of natural selection remained supreme at the close of the nineteenth century, and its application to social problems of history and politics fascinated the philosophers. As to the more markedly social and contemporaneous manifestations of human life, naturalism seemed to lend itself to yet another and still more important series of conclusions. It furnished the basis of that "materialism" which the German socialists caught at so eagerly as definite proof of the hegemony of economic conditions in society and of the complete dependence on them, as a half illusory "superstructure" (*Ueberbau*), of the whole realm of cultural, moral and religious values.

Against this general background the history of the several social sciences during the period naturally follows the most diversified tendencies. The large comprehensive science of social rela-

tions that had been attempted by the Saint-Simonians and by Herbert Spencer under the much criticized title and program of sociology, had in the fullness of the age of liberalism arrived at as dead a level as liberalism itself. In the case of Comte the inborn mysticism of Saint-Simon's school had definitely overthrown the democratic ideal in favor of a new autocracy of scientific leadership; while Spencer's more jejune, but also still more mechanical, panacea of peaceful industrialism has been accused by Albion W. Small, probably with some justice, of being responsible for the remarkable barrenness of English sociological work during the next generation. It is significant of the interlocking of the social sciences that what there was of a new impetus to sociological theory in England came from the neighboring fields of specialistic social inquiry. Patrick Geddes in Edinburgh took up the "regional and civic survey" type of research propagated in France since the fifties by Frédéric Le Play. Edward A. Westermarck in Finland brought the methods of continental ethnology to bear on the problems of the history of the family and sex relations which had up till then, through the methodical shortcomings of L. H. Morgan's American Indian studies, been chiefly used as props for the dogmatism of the German socialists. Political science, in writers like T. H. Green and L. T. Hobhouse, succeeded in outgrowing, by fruitful discussion with continental learning, the traditional moralism of Paley. And earlier and more powerful than all these, comparative jurisprudence gathered the scientific harvest furnished by the administration of the British Empire in Sir Henry Maine's great and at least theoretically lasting discovery of the primitive village community and of the law of progress from status to contract.

In 1887, in Germany, Ferdinand Tönnies, long familiar with Hobbes' realism of social concepts, enunciated his famous theory on the succession of *Gemeinschaft* and *Gesellschaft* that has swayed German sociology and kept it in touch with international sociological thinking ever since. Just enough of a liberal rationalist to put philosophical and statistical generalization above historical vision, of a social critic to denounce liberal complacency, and of a conservative psychologist to feel the foundations of society in the simple and primitive, Tönnies occupied an unusually advantageous position amid the cross-currents of social controversies at home and abroad. But for the moment it was precisely this balance of mind and height of

philosophical aim that postponed his popularity, if not his influence, until well into the twentieth century, while the official leadership of German sociology passed from the Spencerian liberalism of P. von Lilienfeld and G. Schäffle into the hands of the Austrian racial sociologists L. Gumplowicz and W. Ratzenhofer. Children of the same social and political unrest as the economists of Karl Menger's school, these two men, one a Polish Jew, the other a German officer, greatly and deservedly impressed the world of the social sciences by summing up, as it were, the political situation of the Austro-Hungarian state in the striking, if one-sided, formula of racial or national group interests blindly drawing individuals into economic, social and political stratifications. And in this case also, Austrians were certainly offset by what might be called a Prussian or north German group of sociologists, although here psychological finesse happened to be on the side of the latter, after having been practically discarded by racial sociology. There is perhaps no other proof so convincing of the genuine fertility of the historical school as that it should have brought forth, at least indirectly, the first systematic attempts at execution of its proposal to treat economics as part of sociology. Only then the "historical materialism" of Karl Marx began to be replaced by something both more critical and more inclusive than itself. As a pupil of Adolph Wagner, Franz Oppenheimer laid out the ground plan of his "liberal socialist" system of sociology by which the "political economy" of feudal landlordism took the place of capital as a monopolizer of labor, and so might be overthrown by the "pure economy" of harmonious competition. Starting from the ranks of the Schmoller school, George Simmel rounded out the century with that most decidedly economic, and at the same time most systematically sociological, of all his works, *The Philosophy of Money*. Last but by no means least, Max Weber, severe critic though he was of Schmoller's lack of system and easy governmentalism, clearly showed by his early work in ancient economic history and modern agricultural policy that the germs of his later encyclopaedic range of sociological induction lay in the common stock of the "socialists of the chair."

While thus German and Austrian sociology, despite all conflict, was held together by the economic issues of the "social question," the sociology of France after 1871 had, above all, a political and cultural task. With the relapse of Comte into mysticism before its eyes, a new

generation of sociologists was found to resume the exploration of the rational and democratic possibilities of social progress by means of education that had been the driving force of social thought in France from the time of the *encyclo-pédistes*. This impulse became the central idea of the two social philosophies of Gabriel Tarde and Emile Durkheim. Tarde, a lonely worker using the scientific foundations laid down by Spencer, produced what is very imperfectly called, after one of his books, the theory of imitation. (All depends on how imitation is set in motion by the original forces of invention, in a multiplicity of systems that remind one of the "vortices" of his countryman Descartes.) Durkheim, on the contrary, rallying the full forces of national learning and instruction in an effort to create a scientific foundation for a new secular education, went directly to mental laws, creating a *fait social* in the mind of primitive societies, in his search for social levers of equal power with those of the great rival of laicism, the Catholic church.

In America, finally, the first energetic steps were being made by sociology "up from amateurism," as Small has justly emphasized. For the particular advantage, as well as difficulty, of America consisted in the broad philanthropic and humanitarian interest which American churches, schools and societies understood to be the true aim of a new science of society. The later spread of university and even school teaching in sociology, comparing so favorably with that in any European country, did not, it is true, begin until the next century. But meanwhile Comte's and Spencer's projects were patronized by scientists and doctors, ministers and judges, and there was one danger, which had been absent in Europe, that the spirit of patient reasoning and inquiry would be crushed under attempts to lay hold of the new study for the exclusive privilege of dilettante theories or reforming activities. In this situation it was the lasting merit of Lester F. Ward that he created for American sociological research a first model by, at the same time, making "social forces" a part of a comprehensive system of dynamic "nature" and yet never forgetting the "social" character that assigned them a role of their own, and in fact the highest of all roles in the dynamic universe. And it is hardly a matter for blame that Ward should have been inclined to transfer the naturalist's belief in the exactness of his results to the new subject on which he too had ventured as an amateur, and thus to establish his system

too dogmatically as the last word on the subject. Younger men learned from him and went beyond him. Against the Comtian concept of sociology as an aggregate of sciences, Franklin H. Giddings took from Spencer the cue for treating it as an underlying method and basic principle of study, although for him too, and once for all, Ward had broken the Spencerian spell of automatic social evolution. So there was ample room for further development, systematic as well as specialized. W. G. Sumner, who held the first chair of sociology at Yale, began the realistic study of classes and groups of population that might so easily have been neglected in a rapidly standardizing society and yet was destined to become one of the most important branches of applied sociology. E. A. Ross, relative and personal pupil of Ward, was started by him on his laborious career as a field researcher and traveling conqueror of ever new realms of sociological understanding. C. H. Cooley threw the first solid bridge over to the restlessly progressing work of American psychology and in doing so made enduring gains, like Simmel in Germany, in the difficult task of conceptional classification and nomenclature in sociology.

So far as the rest of what we now comprise under the wider notion of social sciences, history, jurisprudence and anthropology is concerned, the time had hardly come for even an outright recognition of their social viewpoint and consequent common relationship. Perhaps even some "progress backwards" was made by them from this viewpoint, under the stress of specialization as well as of opposition to former philosophical attitudes. But even these backslidings in the end served to arouse discussion and to give the period a general character of fruitful experimentation.

Thus in history the new national consciousness inevitably resulted in attempts to unite the knowledge of periods and institutions in a consecutive and comprehensive view of national development, the scientific conceptions of evolution and race, here as elsewhere, entering into a somewhat strange alliance with political purpose and emotion. Heinrich von Treitschke provided the bourgeoisie of the new German Empire with a historical outlook which, in its peculiar blend of monarchical and popular, centralist and racial elements, was the exact reflection of the "constitutional monarchy," while to Austria fell the task of basing the study of the Middle Ages on a new perfected "diplomats" (shaped from documentary sources), as a sort of parallel to the

theoretical technique of the Austrian economists. In Italy Pasquale Villari gave his *Storia politica* to the united nation. In France the standard national history of Ernest Lavisse resolved to a certain extent the historical debate of the parties, while embodying the mediaeval harvests of the Ecole des Chartes. And even in England and America the immense literary and scientific influence of J. R. Green culminated in a liberal apotheosis of the Anglo-Saxon political genius, before the work of John Seeley opened new vistas of imperial magnitude. But despite all this, definite claims were put forward on behalf of a non-political and a "cultural" principle of historical research by W. E. H. Lecky, the Irishman, and on the continent by Karl Lamprecht, who showed perfect willingness to cooperate, in his economic research, with all the other branches of the brilliant philosophical faculty of Leipzig University.

In jurisprudence, too, the stage lights were turned on the German generation that first, after the revolution, dared to incorporate the sum of nineteenth century legal development in a great civil law codification. Otto Gierke, although hardly satisfied with what the new code took up of "Germanist" doctrines, became both an international teacher and a national adviser in the bulky volumes of his *Genossenschaftsrecht*. In a chair at Vienna, on the other hand, Rudolph von Ihering started his brilliant career as a fearlessly modernistic interpreter not only of Roman law, but of the meaning of law generally, in terms of will, purpose and struggle, as opposed to Savigny's view of harmonious organic growth. And it was in an attack upon Ihering's rationalistic analysis of Shylock in *The Merchant of Venice* that Joseph Kohler first showed himself to be a powerful renovator of Hegel's philosophy of law in the modern garb of a universal student of primitive and comparative law. If in this way even the theory of law seemed to end in historical relativity, the science of public law, in the dawn of modern imperialism, was limited by the disposition of its interpreters to rest content with accounting for and comparing factual systems. While Paul Laband and Otto Mayer analyzed the positive contents of constitutional and administrative legislation, the early work of Georg Jellinek began to wander into the historical and comparative field, as did the great schools of R. Dareste and A. Esmein in France.

Last of all, anthropology (a name applied by the classical writers, like Kant, to a quite general, even psychological, knowledge of man)

began to give promise of becoming not only a universal basic social science but also a rival of sociology from the point of view of what purported to be the firmer standing ground of the physiological and biological roots of human existence. An increasing dissatisfaction both with the "objectivity" and the broader human significance of current political history made the effort to write the "history of civilization" or of "mankind"—the old aim of the *encyclopédistes* and later of Buckle—the center of anthropological efforts. Very little of all this has been able to survive on account both of a lack of methodical depth and of an inverse wealth and rapidity of material progress. Medical celebrities, like Rudolf Virchow and Armand de Quatrefages, tried to put to anthropological use the material furnished by the great standing armies of Germany and France, only to quarrel over the latter's rather preposterous theory of a *race prussienne*. More successfully Wilhelm Wundt left medicine to found the first laboratory of experimental psychology in Leipsic, and fully made up for what the philosophers thought his deficiencies in their field by a wonderful and stimulating interest in the whole gamut of social and historical anthropology. In fact he and his Leipsic colleague Friedrich Ratzel, the geographer, became the heads of a rich family tree of German and international schools with all the anthropological and ethnological branches. In contemporary England John Lubbock (later Lord Avebury) concentrated on the problems of the origin of civilization; E. B. Tylor brought back from Mexico the critical and comparative viewpoint that was to inspire the early work of W. B. Spencer and F. J. Gillen on the Australian, and of Franz Boas on the American, aborig-

ines; the Evanses carried the ethnological method into Celtic and Mediterranean archaeology; and J. G. Frazer made a first imposing attempt to take stock of the scattered treasures of folklore. Even comparative philology, which had hitherto given preference to dead languages and written sources, was touched by the impulse of Darwinian evolutionism and tried to join the "natural" sciences, keen on the "physiological laws" of change and relationship, under the influence of Max Müller, August Schleicher and the school of the "young grammarians" in Germany. And curiously enough, racial pride, which furnished the basis of Count Gobineau's protest against English cosmopolitanism at the culmination of the liberal age, drank life instead of death from the rising tide of naturalism and relativism, and in cultural philosophies such as Wagner's and Nietzsche's grew into an inseparable element of the new age of nationalism and imperialism. A striking illustration of this is found in the Russian novelist Dostoevsky, who even in the atmosphere of the Eastern church crowned the life of a revolutionary by fanatic assent to the creed of the pan-Slavists.

A great many short cuts had yet to be proved delusive before all the conflicting elements in the social sciences could be harmonized in John Stuart Mill's conception of political economy as "a branch of social philosophy so interlinked with all the other branches that its conclusions, even in its own peculiar province, are only true conditionally, subject to interference and counteraction from causes not directly within its scope; while to the character of practical guide it has no pretension, apart from other classes of considerations."

CARL BRINKMANN

XI

The Trend to Internationalism

I. HISTORICAL SETTING. From the days when Galileo first looked through his little brass tube, the more profound changes in the conditions as well as in the ideas of humanity have originated in the laboratory or study. It continued to be so in the twentieth century. Science was opening up further unexpected visions of reality that not only were shaking the thought foundations on which men had conceived the physical universe but were being translated into forms of power outmoding the mechanical triumphs of the age of steam. The atom was being dissolved into the electron. Matter itself, the solid firmament, was turning into the inconceivable swift dance of impalpable energies. The elements which had been taken for its immutable and eternal forms were shown by Rutherford and Soddy, following the discoveries of Becquerel and the Curies, to arise through a cosmic process of transmutation. Light and electricity were one with the "substance" of the universe. These speculative triumphs went hand in hand with practical applications. Here too electricity played a dominating part. It submitted to being harnessed without being understood, and it was capable of being utilized in myriad ways. When generated from water power it could never be used up, unlike the resources of coal and oil. It was clean and simple and amazingly convenient. It could annihilate space, for its modes of communication were as swift as light itself. With the aid of gasoline it made possible the automobile and the aeroplane, and it was applicable to every other form of transportation. There seemed no service which it could not provide, no human toil which it could not alleviate. Thus it was performing two functions of peculiar social significance. It was creating a less laborious and yet more complex civilization, and it was bringing the foci of social influence into continuous and immediate contact with one another and with the ends of the earth.

The applications of sciences, progressing in many directions, were the source of new wealth and new economic security. They made practicable the ideal of a minimum standard of living

for whole nations, an ideal which until the later nineteenth century had never been more than a vain dream. In Europe a new conception had arisen of the state's duty in this regard. The example set by Germany in the eighties, in the establishment of sickness and accident insurance for its working population, was extensively followed in the years before the Great War. Austria had quickly accepted the German principle. Now, in a series of acts from 1906 to 1911, it was adopted by England, including workmen's compensation, old age pensions, sickness insurance, and the beginning of unemployment insurance. National provision of social insurance was taking form all over western Europe, in France, in Belgium, in Switzerland, in the Scandinavian countries and in Italy.

Internally the state was adapting itself to the new conditions. Externally it was bound by traditions which refused to yield to the new demands upon it. In the early twentieth century the most flagrant revelation of the "lag" of tradition was found in the obstinacy with which the nationalistic policies of sovereign states refused to recognize the necessities of an international civilization. An international economic system had come into being, and in spite of national trade restrictions was growing always greater. The consciousness of the unity of the modern world was finding cultural expression and was being reenforced by the cooperative quest of science. But the political guarantees of this institutional system were utterly insecure, and the various attempts to found a world order broke vainly against the enthroned dogma of the nation state. There were of course international agreements regulating trade and commerce, telegraph, telephone and wireless communications, patent and copyright, and so forth, but as regards the relations of states themselves to one another no satisfactory advance was made.

The close of the nineteenth century had witnessed the first great gesture of modern states towards the reduction of armaments and the establishment of a "real and lasting peace." By this date the problem of armaments had become acute, owing to the greatly enhanced

burdens of competitive expenditure which the changing technique of warfare imposed in answer to the ambitions and the growing fears of the nations. The First Hague Conference, summoned by Czar Nicholas for the year 1899, disappointed the hopes of those who looked for a resultant reduction of the burden and peril of armaments; and the consolation offered by the establishment of the Permanent Court of Arbitration proved in the event to be a tragic mockery. Moreover the conferees busied themselves, with the vain sedulity which jurists and statesmen have so often displayed in this regard, in enunciating "rules" of warfare. Nevertheless the gesture was significant and the fact that a Second Hague Conference was called in 1907 encouraged the more sober aspirations of those who expected a slower but eventually successful accord towards the peaceful organization of the world. In fact the second conference, which did not include the subject of armament limitation in its program and would not have discussed it at all but for the insistence of the American delegation, was entirely abortive. It is true that it gave further attention to the "rules" of war and the rights of neutrals, by-products whose worthlessness the Great War was inevitably to prove. Nor were more limited overtures, such as the proposal in 1912 of a "naval holiday" between England and Germany, of any avail.

Perhaps it was a mistake to assume that in the complicated jealousies and fears of Europe the reduction of armaments could precede the firm establishment of a true international system. The rudiments of such a system may be found in the arbitration treaties which were in considerable numbers concluded during our period. Many of these, such as the Anglo-French Treaty of 1903, were agreements to refer "justiciable" differences to the Hague Court. In the furtherance of arbitration treaties the United States, which stood happily apart from the European system of alliances, led the way. Roosevelt in 1904 and 1905 was active in negotiating arbitration treaties with the states of the world, though these were abandoned by him on account of senate amendments. But no fewer than twenty-five such treaties were negotiated later by Secretary Root. A notable effort was then made by President Taft to extend the scope of arbitration treaties to include issues affecting "national honor," the previous exception of which revealed the gulf still lying between the code of individuals and the code of nations. But, like Roosevelt, he met with opposition from

the Senate and dropped negotiations. In 1913 a new series of conciliation treaties was negotiated by Bryan, and twenty-one of these were finally ratified.

Meanwhile the European system of alliances remained the controlling factor of international politics. The "balance of power" maintained a precarious equilibrium. The Dual Alliance stood over against the Triple Alliance. The failure of Russia in the Russo-Japanese War diminished the confidence of France, but, on the other hand, the *entente* with England greatly strengthened her position, while at the same time the adherence of Italy to the Triple Alliance was growing doubtful. So the struggle for power went on without abatement until the event of Sarajevo. It took the World War to settle an obscure issue between Serbia and Austria, and long before it ended the issue was lost to sight in the incalculable and unprecedented conflict. Thus in the common disaster of the western world was the interdependence of all nations revealed, and with it the catastrophic futility of those unlimited claims of national sovereignty which refused to recognize the political necessities of the new civilization.

II. DEVELOPMENTS IN THE SOCIAL SCIENCES. The social sciences come so close to the interests and everyday affairs of men that they are peculiarly apt to reflect the prevailing tendencies of the times. At the beginning of the twentieth century the need for social interpretations and investigations was growing more obvious and perhaps more imperative, and in response to it the social sciences were greatly expanding. But they were expanding in the directions and according to modes which the spirit of the age dictated. One great determinant was the triumph of the physical sciences. It was increasingly felt that the social sciences must follow the methods of exact measurement which distinguished the sciences of nature. True, the data of the social scientist were not so amenable to this treatment as were those of the physicist, but this was the misfortune of the former, to be overcome as far as possible by such substitutes for exact measurement as the devices of the statistical method. Social researches accordingly tended to deal with those aspects of the social structure which could be subjected to a quantitative analysis. Economics, being in a favored position in this respect, represented the model which the rest endeavored to follow.

This attitude expressed a healthy reaction

from the confident generalization of the early days of the new sciences. But it was also one with which the age was in sympathy on other grounds. It was an age of experiment, seeking practical utility. It was interested in truth for the sake of results rather than from intellectual curiosity. Truth was a tree that like any other must be judged by its fruits. The Platonic idea that it was a beautiful thing to contemplate for its own sake found little favor. The pragmatic principle found characteristic expression in the philosophy of the age. Philosophy itself became practical. Thus alone could it be saved from contempt as the product of an idle imagination. The teachings of Schiller, of James and of Dewey were all directed against the aloofness of philosophy from the everyday world. And they had close affiliations with the anti-intellectualism which expressed itself, for example, in the *Creative Evolution* of Bergson.

This anti-intellectualism found great support in the tendencies manifested by the young and popular science of psychology. Conduct was discovered to have an emotional and instinctive, rather than a rational, basis. Above all, social phenomena had to be interpreted as the expression of habits and instincts rather than of an abstract principle called reason. This attitude was first emphasized by the psychologists who studied the crowd, like Le Bon or Sighele, or the folkways, like Sumner or Wundt. It was now applied to all aspects of conduct, particularly to ethics and politics and economics. It was made the basis of educational doctrine, eminently by Dewey. McDougall's *Social Psychology*, which first appeared in 1908, was essentially a study of the human "instincts," and had a remarkable vogue. At the close of our period the new psychological interpretation took the more extreme form of behaviorism, proclaimed by Thorndike in his *Educational Psychology* and by Watson in his book which gave the name to this movement.

The working out of these tendencies will be shown as we pass in review the contributions of the various social sciences.

III. ECONOMICS. At the close of the nineteenth century the marginalist doctrine, though subject to revision, still held the academic field. In the hands of men like Marshall it had seemed capable of meeting the complexities of the price system and even of interpreting the non-competitive aspects of the economic order. Accordingly, during our period, many economists

continued to rely mainly on the "marginal method," but the forces of criticism were gaining strength and at its close were already in the ascendant. This trend was encouraged by the increasing devotion of economists to factual research in specific fields, such as population; business enterprise, economic cycles, wage determinations and so forth, in which the assumptions of the marginal approach seemed to be unnecessary or irrelevant. Thus in Germany it was this tendency, rather than any alternative general theory, which weakened the domination alike of the historical and the marginal schools, creating groups of scholars attached to particular problems of research rather than to particular theories. We may cite by way of illustration the work of Harms and his associates in the establishment of the Kiel Institute, devoted primarily to the study of the specific problems of international economic relationships. Again in France, although economists like Aftalion ably upheld the value doctrine of the marginal school, the same tendency was manifested toward more detailed analyses of economic situations rather than synthetic constructions. But in fact the change of emphasis may be said to characterize the age rather than a particular country.

Consequently the theoretical interest tended to center around questions of method and of goal rather than of constructive interpretation. Was the inductive method adequate or was there still a place for general principles? Was the mathematical approach consistent with realistic economics? Was there a field of economic statics where exact principles of the Ricardian or Austrian type could be utilized as distinct from the field of dynamic actualities with its unstable equilibria and changing pressures? These were the questions which the clash of older and newer viewpoints invoked. It obviously precipitated new forms of the eternal methodological problem in the social sciences. In further illustration we may cite the question whether the idea of value itself, the core of older doctrine, should be abandoned, as Cassel was beginning to assert, in favor of the more specific idea of price. And the question which aroused much debate in Germany and elsewhere, whether economics as a science had room for a normative as well as a descriptive aspect, had also to be reckoned with.

The hold of the marginal principle had grown particularly strong in America, under the leadership of J. B. Clark. But here too by the end of our period the critical reaction was dominant.

Certain economists, while adhering in other respects to the marginal school, were influenced by the attacks directed at its psychological basis and refused to accept some part of its doctrine. Thus Davenport rejected the analysis in accordance with which the business entrepreneur evaluates the precise productivity of the various elements united in the process of production, while Fetter denied the hedonistic assumption and contented himself with the simple fact of choice or preference as a determinant of value. But other economists demanded a new orientation of economic theory altogether, joining hands with the critics of European countries who, seeking a new doctrine, remained meanwhile skeptical of the old. The marginalist theory seemed to those critics to be abstract and unrealistic. It appeared to them relevant only to static conditions, in spite of the attempt to adapt it to a "dynamic" society. Marginalism, it was felt, was a timeless theory, as true, if true at all, of the domestic age of production as of the capitalistic; but economic theory must explain the transition from the one to the other. In other words, it must be evolutionary. Critics like J. A. Hobson pointed out that the marginal analysis was least applicable to the most distinctive characteristics of the present economic order. The principle which computed the efficiency of isolable marginal units of capital or labor seemed to them quite unsatisfactory as applied to the "organic" system of large scale production, with its interdependence of units and advanced division of labor. To other critics its principle of subjective valuation appeared wholly inadequate in the light of a more realistic psychology which questioned the hedonistic calculus.

Thus the period became increasingly one of criticism. At its close there remained no dominant theoretical interpretation such as still reigned at its beginning. The field of economic research had widened and offered new opportunities which turned the great majority of the younger economists into specialists in particular branches of the study—in finance, taxation, labor, population, marketing, agriculture, transportation, corporation economics and so on. The practical problems of these branches involved the application of quantitative methods which seemed to many to have little need for the support of a general economic theory. There developed in fact a widespread skepticism regarding the possibility of the kind of economic law which had found its latest exemplar in the doctrine of the marginalist school.

Another tendency of the times antagonistic to clear cut classical principles was the growing recognition that the economic factor was inextricably inwoven in the whole social life, that therefore there was no autonomous sphere of purely economic phenomena obeying purely economic laws. This recognition was widening the range of economic investigation, but it was also making synthesis more difficult. Long before, it had entered the consciousness of J. S. Mill and disturbed the system of thought which he had inherited. The socialists, following Marx, had found a relatively simple way out of the difficulty by giving priority to the economic factor. Loria, for example, sought to establish "the economic basis of the social constitution." But the exploration of these interrelationships tended to show also how the social facts reacted on the economic. Whenever the economist, pursuing these interactions, became thereby a sociologist, as did Sombart or Max Weber, it was perilous to the simplicity of economic doctrine. And certainly it was rare to find a thinker who, like Tugan-Baranovsky, could accept the socialist position regarding the relation of labor to capital and still remain a marginalist.

But if the older type of theory lost influence, new points of view were emerging. What, after all, the critics had shown was that the structure was too complicated to be interpretable under a simple formula, that human motives were too involved for a simple calculus, that the simple assumptions of competition and mobility were in part defeated by the ignorance, prejudice, inertia of the economic individual, by his social involvements and by the growth of anti-competitive organizations. The marginal and classical theories were not so much superseded as modified. If the complexity of human motives and of changing institutions called for a more comprehensive theory, the answer could not be the rejection of theory altogether. Meanwhile the results of descriptive analysis and of quantitative research would provide a surer and broader foundation of facts on which the new synthesis must be built.

It is important to observe at this point that the quantitative analysis which was gaining ground in the early twentieth century was something entirely distinct from the mathematical analysis of "pure" economics. The mathematical economics represented by Pareto and Pantaleoni in Italy, by Moore in the United States, and in part by Edgeworth in England, depended upon hypotheses as clear cut as, and in fact generally

identical with, those of the marginal school. The quantitative economists, on the other hand, tended to abjure all general hypotheses, and where they employed mathematical formulae it was to achieve order and coherence in the presentation and interpretation of statistical data. There is in this respect a striking contrast between, for example, the work of Pareto and that of Mitchell. In Mitchell's work there is an emphasis on the manifold aspects of an inductive process which makes it at once one of the most characteristic and one of the most successful contributions to the economic theory of our period. It is significant alike for what it does and for what it fails to do, as showing not only the fruits but also the limits of the quantitative method. If one feels that there are aspects of the situation which remain uninterpreted, one feels also that this is because statistics, even in the hands of a master, cannot fully reveal the human conduct and human institutions in the study of which it is an indispensable aid.

If we set Mitchell's *Business Cycles* side by side with a contemporary study involving the deductive use of the marginal principle, such as Pigou's *Wealth and Welfare*, the contrast is again illuminating. Pigou thinks in terms of a national "dividend," and the problem is set in terms of the diminishing utility of wealth and of the effects on marginal productivity and marginal utility of a more equal distribution of this "dividend." The social tendencies of early twentieth century England are seen in his treatment of governmental intervention as a mode of reducing marginal inequalities and thereby of increasing the net utility of the total dividend or the total "economic welfare" of the community. The effects of monopoly are treated from a similar standpoint. The whole of his elaborate analysis is dictated by his initial hypothesis, and it alone makes possible the mathematical calculus which he introduces.

In the development of quantitative economics we may find two seemingly opposed tendencies. To some it seemed to involve the abandonment of those considerations of subjective valuation and of social utility which are not susceptible themselves of quantitative statement. The attempts to measure satisfactions, as in the doctrine of "consumers' surplus" put forward by Marshall and elaborated by writers like Wicksteed, were far from convincing. The quantitative analyst generally felt on surer ground when he was dealing with the objective phenomena of the price system, and various writers limited

their range of investigation to this sphere of calculable facts. On the other hand the census, the reports of governmental departments and commissions, and numerous social surveys were providing an increasing mass of statistical data regarding population, wealth and poverty, standards of living, the relation of productivity to hours of labor, the relation of health to occupation and income, and so forth. These data were indices of social welfare and demanded interpretations in terms of their social significance. Here the quantitative analysis was itself preliminary to a different type of analysis. Beyond the curve-fitting and the correlating there lay in wait the insistent questions of the social and economic motives, of the institutional changes and of the modes of living, which are reflected in the statistical facts. A qualitative analysis was needed to supplement the quantitative analysis. For it could not be at all assumed that the changes in the economic index, say of wealth or efficiency, measured corresponding changes in the achievement of social values or even of economic utilities.

Here in fact were involved assumptions of orthodox marginalism against which the advocates of an "economics of welfare" strongly protested. Marginalism had sought to prove that the worker, at least the marginal worker, received what he was economically "worth." Again it had seemingly demonstrated that the utilities derived from different consumers purchasing the same goods and from the single consumer in his disbursements on a variety of goods, were equalized at that terminus of all happy conjunctures, the margin. Moreover the attribution to the wage earner of a "specific product" which coincided in exchange value with the wages of the marginal worker was held by many to offer an interpretation too favorable to the established order of things. Perhaps nowhere were these assumptions more directly attacked than in the writings of J. A. Hobson. In his *Work and Wealth* he claimed that orthodox economics was animated by a too narrow and materialistic interest in the productive process. Against economic utilities must be set social costs, and against economic disutilities there may be social profits. From the standpoint of social economy the values of capitalistic production must be revalued. From this standpoint the fact that the marginal laborer receives his economic due, if it is a fact, is no final argument against an intervention which would raise his reward to a level of decent maintenance.

The intrusion of social considerations was effective also in the broadening out of the scope of economic inquiry. It gave a new interest to a subject like taxation which had hitherto received rather summary treatment. The change of viewpoint and the enrichment of the study are well illustrated by Seligman's works. The same trend is illustrated by the intensive studies of economic institutions and organizations such as were undertaken by the Webbs; by the investigations into social concomitants of industrial change such as those of Sombart, Tawney, Hobson and the Hammonds; and by the researches on the interdependence of economic and cultural phenomena such as the analysis which Max Weber was preparing on the relation of religion and economics.

Of all the economists who revealed this new sociological trend none was more outstanding than Thorstein Veblen. His incisiveness, his irony, his critical reversal of accepted premises, and above all his consistent interpretation of economic and social institutions in terms of technological change, gave his work a peculiar significance. While seemingly aloof from contemporary schools of thought, he formulated, perhaps more profoundly on that account, certain dominant tendencies of the age, and in particular its preoccupation with the mechanical and materialistic aspects of existence. He criticized the prevalent theories in the light of the *Zeitgeist*, and built up a positive doctrine that was certainly, in spirit if not in manner, in harmony with the deterministic evolutionary science of the time. The fact that Veblen influenced so profoundly many of the younger economists and sociologists shows how fully his teaching incorporated, not the traditions, but the working hypotheses, of the period.

To understand Veblen's position in economics, it is necessary to recall his sociological doctrine. To him the great agencies of social change are those which establish new modes of habituation, of "use and wont." These agencies in the last resort are the techniques imposed by the devices which men discover in their efforts to satisfy their primary needs. When the technique changes, the society gradually changes in conformity. In the feudal age the system of production was one of "trained man-power organized on a plan of subordination of man to man." This system expressed itself in the highly personal character of government, in the authoritative and hierarchical character of religion, in the estimation of craftsmanship and personal

dexterity, and so forth. But the industrial age brought new techniques, those demanded by the machine, and again society is transformed, not only in its economic aspects, but in its political institutions and its cultural standards. The new technology destroys the old ideals as well as the old customs. In those spheres which are most remote from the new influences, the old traditions, as of militarism and nationalism, are hardest to dislodge, but they fight a losing battle. The ancient virtues of "patriotic animosity and national jealousy" are close beset by the influences emanating from international dependence and the mechanization of warfare, not to speak of the generally skeptical frame of mind which the machine age induces. Veblen in his numerous works cited instance after instance to illustrate his thesis that the peculiar habits of thought of each age, those which give social relationships their form and character, can be traced back to the peculiar discipline of life which depends upon its technique.

Such a theory was assuredly in consonance with the conditions of the early twentieth century. Its distinguishing feature was not the growth of capitalism but that great advance of mechanization which included capitalism as one of its aspects. That advance had been peculiarly rapid on the North American continent and it was appropriate that the thinker who most emphatically proclaimed its sociological significance should have done so in the United States. The viewpoint of Veblen was in any event clearly related to the pragmatic philosophy becoming dominant in the country.

The application to economics took the form of a general analysis of institutions, critical of the older theories, and descriptive, in a curious style of hard realism, of the working of the economic order in terms of the doctrine just outlined. In its critical aspect it was a challenge that effectively disturbed the older norms of interpretation while it offered a new illumination of the nature of capitalism, of the distinction between pecuniary and industrial motives, of the character of business enterprise, of the significance of a leisure class and of vested interests. Doubtless the economics of Veblen is exposed to criticism on the ground that it is entirely the *exposé* of a point of view lacking in catholicity and narrowed by the ironical temper of a scientifically disguised opponent of the status quo. But no one can deny either the power of the challenge or the keenness of the analysis.

Veblen had given a new meaning to the

"materialistic interpretation of history." The special Marxian formula, which found the root of social change in the relationship between the owner and the producer, had proved too narrow, too dogmatic. The simplicity of the strict Marxian determinism was being abandoned, on historical and psychological grounds alike, although, as Seligman's study showed, the importance of the economic factor as a determinant was being more fully admitted and realized.

A final word may be said regarding the cleavage of individualist and socialist economics during the period. In Europe the number of economists who might be classified as socialists had been increasing, but that term covered an ever wider variety of attitudes. The left wing parties were interested largely in economic ideology, and while the adherents of the Marxist doctrine, orthodox or revised, still held their ground, elsewhere there was a search for a new ideology, of which the chief result was the syndicalist "myth" as expounded by Sorel and Labriola. On the other hand the right wing socialists were less concerned with general theories, and their intellectual leaders were more successful in stimulating the advance of those researches into poverty, unemployment, trade unionism and allied subjects with which the name of the Webbs was already so notably associated. At this end the line between socialists and individualists was losing its sharpness. In England, for example, some of the Fabians, such as Graham Wallas, were socialists under one interpretation of the term and individualists under another. In France the doctrine of co-operative solidarity advocated by Gide, looking toward control over production by associated consumers, was quite distinct from the socialism of the Catholic school, and the latter was far apart from the tenets of the Marxists or of the syndicalists. In truth socialism—and individualism too—had grown protean, a fact which happily was making it more possible to separate the business of scientific interpretation of facts from the no less legitimate but entirely different business of ethical evaluation.

IV. POLITICAL SCIENCE. Toward the close of the nineteenth century there were signs of a very significant change in political science. There was a beginning of that most fruitful experience without which the really great advances in any science never take place, the re-examination of first principles. It may, in a longer retrospect than we possess, seem curious

that the absolutist doctrine of sovereignty, one, indivisible, omniscient, should have endured so long in the face of the separation of church and state, of the triumph of federalism in North America, of the obvious limitations of parliamentary control, and of the confusion and even terror which the practical assertion of that doctrine caused within a civilization inexorably bound by commerce and by culture. As the century closed, various lines of attack on that doctrine were converging, and the twentieth century witnessed the united assault which could not stay the catastrophic fulfilment of the menace inherent in the unlimited state.

Among the considerations which were leading to a reinterpretation of the doctrine of sovereignty none was more potent than the recognition of the role played by great non-political associations, associations which the state claimed to regulate but which it could no longer claim to be merely its creations. The meaning of the separation of church and state was interpreted anew by writers like Figgis, who in his *Churches in the Modern State* distinguished the autonomy of the church in its own sphere from that of the state. But it was the contemplation of the great associations of the economic order which more generally inspired the attack on absolutist sovereignty. "If we look at the facts," wrote A. D. Lindsay in 1914, "it is clear enough that the theory of the sovereign state has broken down." The facts in question included the loyalties evoked and the powers exercised by the corporate groups or voluntary associations within the community, associations that, like those of capital and labor, entered into conflicts on which the state seemed unable to impose its will, while at the same time they united their members in unions that extended beyond the confines of any state. Above all, economic power refused to be the mere subject of political power, and there were salient occasions when it openly or tacitly defied the sovereignty of the state.

These facts found an extreme interpretation in the political theory of syndicalism. Extreme as it was, nevertheless it remains significant of a new attitude toward the state. Conditions had indeed changed when in the early twentieth century the French exponents of this doctrine, Sorel, Louis, Pataud, Pouget and the rest, could regard the state, with whatever exaggeration, as an outworn and rather needless organ, to be supplanted by economic syndicates. It was the farthest reach of the movement of protest against sovereign claims that seemed no longer

realistic. It made the rising doctrines of the guild socialists seem moderate. The latter, like Penty and S. G. Hobson, would merely limit the state's sphere on the ground that the business of economic production was already controlled by other forces and could be far more satisfactorily administered by functional or occupational organizations, the reconstructed guilds or "parliaments" of producers.

The alleged economic impotence of the state was also made the basis for assaults on its sovereign independence in international affairs. It was effectively expounded by Norman Angell in his *Great Illusion*, which showed the economic futility of the last resort of sovereign power—war. It was brilliantly illustrated by H. N. Brailsford, who in his *War of Steel and Gold* exposed the powers of world finance moving behind the curtain of diplomacy. The same argument was naturally adopted by the socialists everywhere, Oppenheimer and Loria being important exponents of it. The Marxists, it should be observed, made it the ground for a reconstituted state rather than for a limitation of state powers.

A more conservative reenforcement of the attack on the older sovereignty came from the jurists who were revolting from the standard of Austin. Jellinek brought out some of the limitations to which state power was subject because of its legal (*rechtlich*) character, though he still thought of constitutional guarantees as the self-imposed limitations of the state. The Dutch writer Krabbe went further. He set the old idea of the state as a power system, with sovereignty inherent in it, over against what he regards as the modern idea, according to which government is conceived as an organ of society for lawmaking. This latter conception makes government an agent only, subject to the law which it enacts or administers, the real sovereignty being that which is inherent in law itself, which derives from the loyalty to the code. To Krabbe it is not in the last resort the will of government or the will of the majority which has authority. It is law itself, an impersonal spiritual (*geistig*) power whose regulations express the social valuations of the community, in so far as these can be formulated and confirmed through legislation. The basis of sovereignty broadens as the state moves towards democracy, but the limits of sovereignty become more apparent, since in major concerns the law can regulate only in so far as a definite social valuation, capable of legal statement, is expressed.

The followers of Maitland and Gierke applied the juristic doctrine in another direction. To them the state was a corporate "personality" distinguished from others as the organ of law-making and law enforcing, deriving its character from the juridical principles of which it is the author and interpreter. This doctrine admits two facts essential to any realistic theory of the modern state, the first being that the state is not identical with the community of which it is an organ, and the second that the other corporate groups in the community have likewise a function and a sphere which in some ways limit the function and the sphere of the state. Just what is, no less than what should be, the relation between them, became the crucial problem of modern political science. While some authors like Dicey admitted limitations on sovereignty in practise without really abandoning the older theory, others made these practical limits the basis of more radical interpretations. The principle that the state was a source and sanction of social order was called in question. Some, like Duguit, sought another ground of unity altogether, finding it in the "social solidarity" of men, a diffused sense of interdependence which supported the various forms of rights and obligations accepted in a community. Others, extending the federalist idea from territorial to associational groups, sought for a working equilibrium of powers in which no one could be called supreme in all things over the rest. To others the very postulate of unity, of which the state had been hitherto regarded as the main bulwark, was no longer admissible, and thus the way was prepared for those pluralistic theories which, in keeping with the anti-intellectualistic trend of the age, were making headway as our period approached its close.

Reviewing the period as a whole, we recognize the vitality of political thinking, critical and constructive, which pervaded it. It was characterized by significant and fruitful efforts to break away from traditional interpretations of the state and to formulate in theory the results of the accumulated political changes of an era. It is true that political science was undergoing the general changes characteristic of social science throughout the period. The realistic study of political phenomena, aided by the new interest in psychology, gave us works like Michels' *Political Parties* and Ostrogorsky's *Democracy and the Organization of Political Parties*. The development of social legislation, anti-trust legislation and so forth, led to numerous researches,

practical and speculative, on the economic activities of the state. The comparative and historical study of political institutions was advanced. But besides the industry of research there was the questioning of old hypotheses, the endeavor to see the state itself in the light of a new time. This more speculative aspect was far less in evidence in America than in Europe. But it was the aspect which gave its historical character and its profounder interest to the political science of the period. And if in an age of practical concerns, looking askance on speculation, some justification was needed for this engrossment in first principles, it came with a vengeance when the World War revealed to those who had eyes to see the scarcely imaginable consequences of the enthronement of doctrines which only the blindness of tradition could have imposed on an alien age.

V. JURISPRUDENCE. Perhaps no division of the social sciences retained so tenaciously a formalistic attitude toward its subject matter as did jurisprudence. Not only did it stand relatively aloof from the developments in the other social sciences; it seemed also to be little influenced by the ferment of thought concerning the state, even though it was itself an essential part of any *Staatslehre*. It is true that in the later part of the nineteenth century the philosophical bases of legal formalism were undermined by those jurists who, like Maine and the writers of the continental historical schools, drew attention to the preconditions and origins of modern codes or, like Ihering, sought to interpret law in terms of social aims and social adjustments. It is true also that the significance for law of the new multiplicity of associations, of "corporate persons," was brilliantly expounded by Gierke and his followers. But these interpretations scarcely penetrated the law schools or the law texts, nor were they effectively applied to the actual problems of substantial law. In England and America the analytical school of Austin, enclosed within the rigid walls of an absolutist doctrine of sovereignty, still dominated legal thought.

The early years of the twentieth century mark a fairly definite change. It became more apparent that analytical formulae were inadequate to explain the judicial process; that, for example, the decisions of courts were not conclusions drawn with inevitable logic from the major premise of the law and the minor premise of the case "subsumed" under it; that the law was not

a rubric the interpretation of which remained clear and unshaken by the currents of the age and the social valuations of the judge; that in fact its most important categories, like "freedom of contract" and "due process," were highly elastic and uncertain, not to be defined *in abstracto* but only in their concrete application to perplexing social situations wherein other legal categories might also claim to direct the decision of the court. It became apparent that the categories themselves were not so self-sufficient as they had seemed to the lawyer who regarded them as the explicit "commands" of the sovereign, and that the code as interpreted by the courts was a far more subtle and accommodating reality than the code as enacted by the government. It became apparent that even so the law of the court lagged behind the march of social requirements. And if this were true of municipal law it was true in a more tragic manner of that body of rules, not properly to be dignified with the name of law, which stretched over the no-man's-land between national frontiers.

In the consciousness of these defects, alike in the theory and in the form of law, new schools of jurisprudence took their rise. It was inevitable that in their efforts to reform the science of the law they should at length have felt the impact of the other social sciences, the recognition of which was already producing results in other fields.

The new attitude was well expressed by Ehrlich in his conception of the "living law." The law lived as it worked on the purposes of men, as it affected their social relations, as it concretely operated within the frontiers of a people. It lived as it revealed itself in judicial interpretation, in the outlook of the judge, which, perhaps, as Wurzel and Bozi endeavored to show, could be made to reveal the very spirit of jurisprudence. Obviously this tendency brought jurisprudence under the influence of the disturbing relativity of psychological inquiry.

Nor did the new schools content themselves with a broader, more humanized interpretation of the juristic facts, including the juristic "mind"; attacking the absoluteness of the legal formula they attacked also the absoluteness of that conception of "right" or of "justice" or of "natural law" or of "equity" which jurists of all times had postulated as the ethical foundation of law. The end or object of law came to be viewed as relative to the social needs, interests

or demands of the age. Stammeler and Kohler prepared the way by emphasizing the idea that law was the product of social conditions in the past, laggingly adjusted to the social ideals of the present. This adjustment was achieved in part by changes in the code but in great part by judicial reinterpretation, in the light of the civilization of the present, of the major principles of the existing code. It was not enough, in applying the law, to go back to the conditions of its original formulation and to the motives of past legislators and constitution makers, still less to rest judicial determination on a logical analysis of the ancient letter of the code.

Here obviously was an outlook which, while open to critical attack on the ground that it weakened the necessary fabric of the law by making it depend on the variable and perhaps arbitrary conception of social trends and interests entertained by individual judges, nevertheless gave to law a more realistic function and a greater social responsibility. It brought into clearer light what the courts were actually, often in a fumbling, semi-conscious manner, attempting to do. It created a demand for a more explicit statement of the principle underlying this practise, and various theories were born as to the manner in which the law seeks to envisage the conflict of claims and interests, responsibilities and rights, which arise out of the changing social circumstances of the age. Above all it gave an impetus to the study of legal reform as a proper concern of the jurist. A new interest arose in the potentialities of law as a social agency; in the juridical tasks of governmental boards, seemingly executive in character; in the application of law to meet the always divergent situations of individual conduct; and at length in the problems of preventive justice.

In this development certain American jurists took an important part. The leader of the movement was Roscoe Pound, who in 1911 had proclaimed "the need for a sociological jurisprudence," and had already begun that series of eminent contributions which found the reality of law in its expression of the conditions, modes of thought and moral attitudes of the age. Within the range of these the law was "alive," within these limits it won the authority and obedience which in fact alone entitled it to the name of law. Nowhere has the pragmatic tendency of American thinking been applied more effectively than by Pound in the interpretation, and by Mr. Justice Holmes in the direct application, of a "living law."

VI. SOCIOLOGY. The period of early and rapid growth already past, sociology in the United States was encountering at the beginning of the twentieth century some new and serious problems. It was feeling strongly the impact of other expanding social sciences, particularly psychology and anthropology. The dominance of the "psychological approach" was manifested in the writings of various sociologists, such as Ellwood and Ross. Attention was directed to the study of the social attitudes, social responses, social "patterns" of the individual, and this study, while it enriched the materials on which sociologists were at work, introduced also a degree of hesitation and even of confusion respecting the actual sphere of sociology. It was curiously easy to pass from the standpoint of the sociologist, with his interest in social relationships, to that of the psychologist, whose interest lay rather in the individuals so related. The psychological phenomena, the attitudes and reactions of individuals, their social relationships, are the conditions of the sociological phenomena and as such of vital significance to the sociologist, but they are not themselves the peculiar phenomena which constitute this field. There still remains the study of social relationships themselves, the institutions and organizations of society.

The impact of anthropology had also a disturbing as well as an enriching effect. Anthropology had developed the concept of the culture stage and the culture area. It included in the concept of culture the whole array of practises, techniques, habits, arts and crafts, beliefs, ideas characteristic of the group under consideration. Sociologists tended to regard sociology as equally comprehensive and thus were in danger of losing the focus of their proper study, that of the social system within which and through which these cultural phenomena were manifested. The admirable work of Sumner in his *Folkways* was nevertheless more valuable as descriptive anthropological material than as a systematic contribution to the "science of society." The work of W. I. Thomas, another distinctive pioneer in his own field, was chiefly concerned with the psychological reactions of individuals of particular types within particular social situations.

In America comparatively little attention was devoted during this period to the fundamental problems of general sociology. The pragmatic tendency which was now characterizing American thought, nourished in this field by a grow-

ing revulsion from the too easy generalizations of the period of Ward, was not propitious to the formulations of first principles. Apart from Veblen, who stood by himself and whose signal contribution has already been indicated, the most noticeable workers in this field were Baldwin and Cooley. They both revealed, though from different angles, the profundity of the relation between the personality of the individual and the social milieu. Cooley in addition brought out the significance of the small group, the face-to-face group, as a socializing agency. His two books, *Human Nature and the Social Order* (1902) and *Social Organization* (1909), retained, more than those of any other writer who appeared within this period, the distinctive quality of sociological investigation. For Cooley the group with its institutions was a primary datum, not to be resolved into the attitudes of the individuals who compose it. Its structure as a group, its influence on its members, the way in which the group itself changed or developed as its members changed or developed—these phenomena, the essential sociological phenomena, were to him of primary importance.

In England during our period the specific study of sociology was almost confined to a small group associated with the University of London. At this center a sociological society was formed, with the *Sociological Review* as its organ. The leading members of the group were Hobhouse, Wallas and Westermarck, although the work of the last mentioned belonged more nearly to anthropology. Hobhouse was the most prolific writer of the group, but many of his contributions belonged rather to the fields of ethics and politics and nearly all of them might be classed under the rubric of social philosophy. He was particularly interested in applying the evolutionary principle to society, tending to regard the process of social evolution as revealing the gradual realization of those liberalistic ideals of which he was a persuasive and broad-minded advocate. He was apt in consequence to identify social evolution with social progress. The more "evolved" society was that in which there was greater "mutuality of service," a wider cooperative harmony, greater control of mind over environment, and a greater liberation of human purposes within the order of society itself. To him sociology was a "vitalizing principle" of synthetic social interpretation. Hobhouse employed this principle with much insight, although his treatment remained exposed

to the criticism that it rested on certain assumptions regarding the rationality of human nature and that it selected from the conflicting variety of social phenomena those which were in accord with his initial hypothesis. The only way to meet this criticism was by a comprehensive analysis of the social characteristics exhibited by groups representing, according to some objective criteria, "higher" and "lower" stages of social evolution. Realizing the significance of this alternative method of approach, Hobhouse cooperated at the close of our period with Wheeler and Ginsberg in a descriptive and statistical survey, the results of which were published in the volume entitled *The Material Culture and Social Institutions of the Simpler Peoples*. The contrast between the two modes of approach is illuminating. The descriptive analysis of the latter work brought out the lack of any simple correlation between the "higher" social stage and the nearer realization of those ideals which were summed up for Hobhouse in the concept of social progress. It showed the necessity for distinguishing what Hobhouse did not always adequately distinguish, two equally legitimate but by no means identical objects of social research, that which is concerned with the factual direction of social change and that which seeks to trace the mode and the degree in which changing social forms reveal or embody some type of social ideal.

The work of his colleague Graham Wallas followed in some respects an opposite trend from that of Hobhouse. Wallas was no system-builder. A sympathetic and keen observer, he was always seeking for principles on which to build a science of society, but his success lay rather in his suggestive interpretations of this or that aspect of the changing scene. He was much influenced by the psychological theories of the age, and his first important work, *Human Nature in Politics*, had for its theme the non-rational motivation of human conduct in the working of democratic institutions. It was significant that his work was contemporaneous with McDougall's *Social Psychology*, a very influential volume which presented in systematic fashion psychological premises for the most part in harmony with Wallas' conclusions. But Wallas did not rest satisfied with his earlier exposition, and in his next work, *The Great Society*, he dealt with the organization of a complex modern society as a problem set for the human intelligence in its quest for social welfare. This more constructive study was signifi-

cant, apart from its shrewd appreciations of particular social situations, chiefly as presenting in a convincing and felicitous manner the problem of the adjustment of the social system to the primary needs of human nature.

Sociology in France had been following distinctive lines. While the influence of Comte may still be traced in the Durkheim school, an opposite tendency, that expressed in the regional studies of the Le Play school, had gained ground. This tendency continued into the twentieth century. One outgrowth from it was the branch of study known as "human geography," of which the chief exponents were Brunhes and Vidal de la Blache. These writers envisaged larger areas than did Demolins and the school of *la science sociale*, and were especially concerned with the interaction between geography and social activity. From this point of view they may be classed as sociologists rather than geographers, since geography provided rather the mode of approach than the object of interest. It was chiefly another method of grouping and studying the complicated array of social phenomena whose wealth of forms and interactions is at once the incentive and the despair of the sociologist.

The interaction of psychology and sociology, so characteristic everywhere of this age, took a peculiar form in France. There a group of writers associated with the periodical *L'Année sociologique* carried to its logical conclusions the old notion of a "group consciousness" or "group mind" which in some way has a reality other than that of the individual mind. In order to establish this notion they resorted to the phenomena of primitive society. Primitive religion, for example, is a set of "collective representations"—which means that it expresses the ideas that spring from the emotionally charged contacts of the members of a group. Its character, in other words, is not to be understood from the standpoint of the psychology of the individual. It reveals the mentality which social beings possess because they are socialized, because they participate in common situations. We begin with collective ideas—they are the stuff of primitive thought—and at length attain individual ideas, as in the thinking of civilized man. The exponents of this principle, Durkheim, Lévy-Bruhl, Hubert and Mauss, differed in one important respect from such advocates of the "group mind" as the Hegelian mystics, for example, Bosanquet, or the nationalistic psychologists of the McDougall school. For Durkheim

and his followers regarded the group consciousness as a primitive mode of thinking which civilized man had in part outgrown, whereas the latter made the "group mind" the higher, more enduring reality. But in either form the doctrine of the "group mind" has been vigorously challenged.

It would unduly extend this survey to include the sociological movements in other countries, such as Russia and Italy, where nevertheless considerable activity was shown. But in conclusion something must be said of the highly significant developments which were taking place in Germany. Here the question of fundamental method, as distinct from exploratory technique, was specially prominent. Was sociology, for example, a special science dealing with an aspect of social life or was it a general science of society corresponding to biology in the organic sphere? Simmel had sought to delimit its field to the abstract forms of interaction or relationship, though his own remarkable *Soziologie* transcended his theoretical limits. He had held that social forms, such as subordination and superiority, could be studied apart from the different media, economic, political, religious and so forth, through which they were manifested. Against this view there arose a considerable volume of protest, expressed by Spann, Wundt, Oppenheimer and others. On the other hand there were various thinkers who were stimulated by Simmel and recognized the cogency of the contention underlying his exposition. They felt that society as such was a challenging object of study but that in order to advance the study it was necessary to distinguish the essential or peculiar or universal attributes involved in social relationships and conduct. In this respect German sociologists as a whole presented an interesting contrast to American sociologists. The latter were inclined to invade the vast new territory without much concern over strategy, trusting to the tactics of the behavioristic and the statistical technique, whereas the former premeditated much and long over the best method of occupying the land.

The resulting *Methodenstreit* was no mere logomachy. If sociology was a real science, it was important to discover its sphere. Many representatives of the special social sciences, like Troeltsch and Vierkandt and Oppenheimer, were crossing these accepted boundaries and becoming sociologists as well. It seemed incumbent upon them to define their new posi-

tion. This task made a special appeal to the speculative scholarship of Germany. Besides, if, as writers like Heinrich Rickert asserted, there was a great distinction between the sciences of nature and the sciences of "the spirit" (*Geisteswissenschaften*), that might certainly involve differences in their respective approach and method which were well worth looking into. The various doctrines which resulted were often no doubt too extreme in opposite directions. But the respective claims of the "scientific" and the "historical" schools certainly made the problem clear, and the challenge which each gave to the other was productive of genuine results. These results, however, were scarcely manifest until a later period, when the main works of Vierkandt, von Wiese, Oppenheimer and Max Weber appeared.

VII. ANTHROPOLOGY. Anthropology, like sociology, has been faced with the task of finding its place in the realm of sciences. From the first it straddled the fences distinguishing the "natural" from the social sciences. In its biometric and ethnological researches it entered into the regions of physiology and anatomy and the wider spaces of biology; in its cultural researches it included all the phenomena expressive of human mentality, such as art, language, religion, social organization, technique. In fact its subject matter was marked out for it not as a definite content but as the whole complex of human phenomena wherever this complex was not too elaborate and diversified to admit of some unity of treatment. If civilized man with all his multifarious works resisted such treatment, at least primitive man seemed to present a more manageable problem. Besides, the principle of evolution offered a key which was eagerly grasped by the pioneers, such as Spencer and Tylor. Social groups by its aid could be classified according to cultural stages, and all the variety of phenomena they displayed could thus be reduced to some kind of order.

What the anthropology of the early twentieth century did was to overthrow the simplicity of these categories, to show the disturbing heterogeneity of primitive society and the difficulty of applying any universal stage-formula that would fit the facts, to seek for new concepts in terms of which complexes of human phenomena could be grouped, and to essay new methods which would express the relation of one complex to another. The richer materials of anthropological investigation provided by the scientific

observations of many more or less primitive peoples, from the Australians to the Eskimos, from the Melanesians to the American Indians, undermined certain of the evolutionary assumptions of earlier anthropologists. Wundt had already, in his *Folk-Psychology*, laid stress on the accidental, irrational, seemingly arbitrary origins of the endlessly variant customs and myths of primitive peoples. He had discovered in the emotionally charged atmosphere of group association the primary conditions of cultural expression. The anti-intellectualist reaction now found a peculiarly congenial field in anthropology, partly because the attitudes and beliefs of the "savage" presented an array of contradictory and apparently irrational fantasies which the civilized investigator could regard with critical objectivity, partly also because the confidence displayed by the anthropological pioneers in simple schematic constructions of human evolution was confounded by the amazing variety of anthropological fact.

An extreme development of the new tendency was exhibited by the French school of Durkheim and Lévy-Bruhl. The former in his work on *The Elementary Forms of the Religious Life* and the latter in his two books on primitive mentality insisted on the "pre-logical" character of every man. Primitive ideas and social observances arose, according to them, out of the mystical uncriticized impression which the forces of nature made upon primitive man. Above all, these ideas were the results not of individual reflection but of the contagious influence of the group as it worked upon suggestible minds that cared nothing for the laws of logic. The savage, according to Lévy-Bruhl, construed experience in accordance with an illogical "law of participation," while the civilized man accepted the logical "law of contradiction." Durkheim and Lévy-Bruhl were criticized as drawing too sharp a distinction between primitive and civilized thought. But much of the criticism was based on the argument that the irrationality imputed by them to the savage is also characteristic of mankind even in the heyday of science. What men took for reasoning was more often "rationalization," and the illustrations of it which Boas, for example, presented in his *Mind of Primitive Man* seemed near enough akin to the ways of civilization even before the Great War afforded its profoundly impressive object lessons.

Some anthropologists, denying the existence of sheer distinctions of mentality between the

primitive and the civilized, went so far as to deride the principle of evolution altogether. Thus Goldenweiser, in his *Early Civilization*, spoke as if evolutionism in anthropology were entirely discounted, although it was Darwinism that first gave anthropology its inspiration and almost its *raison d'être*. Others attacked the evolutionist hypothesis at particular points. Westermarck criticized the evolutionary schema which represented man as passing from promiscuity to monogamy by maintaining that monogamy was primordial in the human race, though his evidences, as Briffault showed much later, were themselves far from satisfactory. But in this period the outstanding critic of the whole principle of cultural evolution was Graebner. He substituted for it the theory of "diffusionism," of which he was the unrestrained advocate.

To Graebner cultural resemblances were mainly the results of contact and adoption. He sought to trace the lines or waves of diffusion by an elaborate study of the material items of culture. (It is worth while noting that it was also in terms of the material culture that contemporary writers who retained the evolutionary hypothesis, like Müller-Lyer, built up their system of culture stages.) Graebner discovered a vast network of diffusion transcending the limits of island and continent, and worked out, with supreme faith in the universality of his principle, great circles and layers of culture. This doctrine was accepted by the English anthropologists Elliot Smith and Perry, who regarded culture as radiating from one center and were not deterred by the paucity of evidence from the sweeping conjectures as to the mode and character of this supposititious process.

Rivers, an anthropologist of great promise, adopted the diffusionist principle with more caution, particularly in his remarkable *History of Melanesian Society*. He was acutely aware of the difficulties of interpretation and of the complexity of the conditions under which culture accumulates and changes. He realized, as Graebner failed to do, the psychological preparation requisite before an item of culture, especially a non-material item such as social organization, can be successfully "borrowed." He recognized also that "borrowing" may change the character of the adopted item. But he came nevertheless to the conclusion that contact is the spring of the human progress in which he definitely believed. In his application of this principle he showed great ingenuity, and he

certainly exposed himself less than the other members of his school to the general criticism which was brought against them, namely that, apart from their too easy acceptance of conjectural adoptions and borrowings, they conceived of culture too much as a series of discrete items, and failed to appreciate the integrity of a culture which, resultant as it is of many factors, yet expresses the psychological solidarity of the group.

While the controversy over diffusionism raged, the study of anthropology was being advanced by numerous specific researches. For this work the United States offered unusually favorable conditions because of the presence within it of Indian tribes whose primitive character was not yet wholly submerged by the advance of civilization. It was therefore appropriate that a leader in anthropology should have arisen and founded a school in America. That leader was Franz Boas. It is significant also that his school should be characterized by a principle of method rather than by one of interpretation. In effect Boas took the following position: Let us make no postulate of evolutionism or of diffusionism or of environmentalism, but let us use any one of those concepts wherever it best fits the facts. Let us begin with definite geographical areas within which a type of culture predominates, such as that of the Kwakiutl. Let us intimately investigate the totality of cultural factors within it, seeking the historical processes of which they are the resultant, seeking also the psychological unity on which they no less depend. The different factors will be variously exhibited, variously related, from tribe to tribe, and thus will lead to a comparative study of cultural aspects, of the mode of assimilation of common features and of the significance of differences. We thus discover the conditions and limits of the culture area, and give concreteness to the idea of a culture pattern in each case, which incorporates and modifies to its own likeness the accretions, introductions and novelties accepted from without or rising from within. The culture area will then be seen as a whole in its geographical setting and in its relation to other areas.

This was the working principle which guided the series of notable researches conducted by Boas and by the representatives of his school, such as Wissler, Goldenweiser and Lowie. It stimulated the exploration of many aspects of primitive custom, ceremonial and myth among the Indian tribes. It encouraged the study alike of single items and of complexes of culture, with

the aid of linguistic and other direct modes of approach. As a historical school no doubt it revealed the limitations of the "historical method," as these were revealed also in economics and other sciences. For a science is never content with working principles; it seeks also synthetic principles interpretative of the phenomena which it examines. From the latter the historical school shrinks, and therefore it can never hold the field alone. If old generalizations prove inadequate, nothing is more assured than that the synthetic spirit of science will seek for new ones.

VIII. HISTORY. It was an old established convention that when an author set down the record of change in the economic order he was accounted an economist, when he traced changes in religious or philosophical thought he was a theologian or philosopher, but when his main theme was the record of political change he was *par excellence* a historian. Certain assumptions underlay this distinction which, long before attacked by writers like Voltaire, began to be vigorously challenged in the later nineteenth century. Why should the record of dynasties and of constitutions be regarded as supremely historical? Did not such an attribution assume an unwarranted causal priority of the political event, if indeed history was the study of those changes which most affected the life of man and ushered in the present order of things? Did not these political changes depend upon social and economic changes in such wise that, abstracted from these, their origin and significance were misinterpreted? The machine age was teaching its lessons. It was defeating not only the "great man" theory of history, not only the individualistic interpretation of political transformations, but the whole doctrine of the preeminence of politician and diplomat and military general and constitution maker in determining the destinies of mankind. "History," said the scientist Fabre, "celebrates the battlefields whereon we meet our death, but scorns to speak of the plowed fields whereby we thrive. It knows the names of the king's bastards, but cannot tell us the origin of wheat. That is the way of human folly."

All the social sciences, as well as those natural sciences whose applications most directly affected human life, were pressing home the lesson. Geology and archaeology were vastly extending the time span of history. Anthropology was revealing the significance of culture changes. Geography was showing the dependence of

civilization on the territorial environment. Psychology was demanding that historical interest be directed to the process of collective thought, the mass movements of opinion as revealed in custom and tradition. Economics and technology were claiming that behind the changes of social usage and institution lay as prime movers changes in mode of production and in control over nature. Under the manifold impact of these influences the traditional conception of history seemed no longer tenable. It was no longer enough, for those who claimed to tell some portion of the story of mankind, to add to an overwhelmingly political account a perfunctory chapter or two on scientific or economic developments. If for no other reason, the idea of the economic interpretation of history had bitten too deeply into the consciousness of those who had witnessed the social transformations of the industrial revolution.

The resulting controversy on the nature of history was carried over into the twentieth century. It raged particularly in Germany where Lamprecht was the protagonist of the view that in proper perspective history was culture history, that the essential changes were not those which occurred in the political structure or were engineered "from above" by governments, but those which occurred in the ideas and modes of living of the people. In this position Lamprecht found able supporters such as Gothein; but his own *German History* was sharply criticized both by the state historians who disputed his theory and by the specialists who challenged his competence. Lamprecht's best known answer was that offered in his series of lectures delivered in 1904 in the United States and published under the title *What is History?* In this volume his insistence on the new historical point of view was more important than his own exhibition of its results, for in seeking to show the necessity for the comprehensive study of all aspects of life he was led to make doubtful generalizations regarding the psychical manifestations of successive periods. Nevertheless the work of Lamprecht was both fruitful and influential. He insisted that history be more than a description of events, that it must be an explanation of change. He insisted that history is a unity and that the unity of history derives from the unity of society, responding through its institutions and varied modes of expression to the manifold interdependent conditions under which it lives in every age.

The work of Lamprecht was very timely. The

defects of his own work showed how difficult was the task which he imposed on the historian. It involved him in the consideration of problems of social interactions which were beyond the generally accepted limits of historical study. It is true that Marx had already flung a challenge to the writer of history; but Marx had also formulated a simple dogmatic solution which the orthodox historian had generally rejected. Lamprecht offered no such "key" to history. He raised a problem rather than solved it. How should the historian achieve this unified picture of civilization which Lamprecht proclaimed the great desideratum? And how should he deal with the problems of social causality when he limited himself to his old task of political historiography or to any of the special histories which he might seek to present? Was description—*wie es eigentlich gewesen sei*—the allotted task of the special historian, and explanation—*wie es eigentlich geworden sei*—the business of the comprehensive historian of culture?

The problem of historiography brought forth the comprehensive survey by Gooch entitled *History and Historians of the Nineteenth Century*. While this volume offered no definite program it showed the trend toward a more comprehensive view of the content of history. It showed also the necessity for the cooperation, in the production of a true picture of the course of civilization, of the specialists of various nations in the various departments of historical study. Finally it suggested that in the search for historical truth there was involved a profounder quest than that which arrived at new or more accurate facts, namely the quest for laws expressive of the direction which, beyond the multiplicity of events, the drama of human affairs might be shown to reveal.

Gooch had complained that the philosophy of history was not keeping step with the advance of historical research. While Lamprecht was insisting on the principle of *Kulturgeschichte* he had not adequately realized the problem of appraisal and of method which it involved. Of the few writers who tackled this problem none did so with more insight than F. J. Teggart, who was particularly conscious of the historical process through which our modes of interpretation themselves develop.

The broader concept of history found a number of strong advocates and exponents, among whom may be mentioned specially Seignobos, Pollard and Shotwell. It was popularized by Robinson and Barnes in the United

States and by Marvin in England. Other writers, such as Beard, contributed to the new synthesis by emphasizing neglected factors. No author was more influential in this regard than Robinson, who in *The New History* and other works dealt freshly and vigorously with the older traditions of history writing, insisting that history must seek to interpret all that we know or can learn about the past of mankind and that beyond events there lie causes which the historian cannot neglect without peril to his claim as scholar or scientist. Such claims were fortified by the numerous studies of various aspects of the human record which were appearing in many lands. It is not possible in this brief survey to mention these fruitful contributions. Suffice it to say that they ranged from Eduard Meyer's great *History of Antiquity* to Merz's *History of European Thought in the Nineteenth Century*.

In conclusion it may be observed that all these movements were bringing history into new relations of interdependence with the other social sciences. The historian no longer had a field of knowledge fenced off as his own. He was dealing with the materials provided by anthropology and economics and geography and all the rest. What remained distinctive in his task was the mode of approach, the aspect from which he treated them, and the form of the synthesis into which he brought them. The historian was discovering the same lesson which the psychologist and the economist and the sociologist were also learning, that in the closely interwoven texture of social life social science has its province demarcated not by frontiers set up by nature but only by the special objective with which it enters the common field. If from its own angle it contributes to the understanding of the life of man, that, and perhaps that alone, is its title to existence.

IX. CONCLUSION. The period which we have just passed under review differs in the retrospect from almost all other periods of intellectual activity because of its abrupt and epochal termination. The sudden diversion of energies to warfare on a gigantic scale inevitably made a profound impression. The optimistic regarded it as an apocalypse whence might arise a new heaven and a new earth, the pessimistic as the downfall of a civilization. Nevertheless its permanent influence on the intellectual life of the nations may well be exaggerated. Apart from its momentous though contradictory political results, as exhibited particularly in Russia, in

Germany and in Italy, it is doubtful whether it did more than temporarily interrupt the deeper processes of social change. Thus the same influences which before its onset were making for the fall of the birth rate, for the decline of dogmatic religion, for the dominance of finance over industry, for the spread of economic consolidations, for the growth of urbanization and the development of the mechanical basis of civilization, continued to act in full vigor in the post-war epoch. The conclusions of those who found the conditions of social change, not in violent convulsions, but in the gradual processes which give man new controls over nature, seemed to be justified by the event.

What had been most obviously changing during the epoch in which our period falls was the material basis of civilization. It was these changes which underlay the trend of the age

toward internationalism. It was the contemplation of these changes and their immediate results which inspired its social philosophies, and fostered its mechanistic interpretations in biology and psychology. Here was the source alike of its optimism and of its occasional pessimism. It gave support to the idea of continuous social progress moving together with the growth of control over nature. And it was from this that those thinkers reacted who saw in mechanism a tyrant and not a servant, who denounced the times as materialistic and unspiritual. *Man versank rettungslos im Stoffe*, said those who, like Lamprecht or Tagore or Tolstoy or Inge, sought for ideals in the past or deplored their absence in the present. Nevertheless it was no accident that the belief in the reality of progress was itself a characteristic of the age.

R. M. MACIVER

XII

War and Reorientation

I. INSTITUTIONAL AND INTELLECTUAL BACKGROUND. The war years were for the social sciences singularly barren in systematic ideas. There was neither time nor energy during the years of fighting for the continuance of the academic theorizing of the pre-war period. When every existing structure had been disrupted it seemed unavailing to continue the process of system building. The overwhelming nature of the disaster that had befallen civilization imposed a sense of futility upon the professional scholar. Only here and there one might be found who proceeded insouciantly with his demonstrations, like Archimedes drawing his circles in the sand during the sack of Syracuse.

The paralysis of effort in the direction of theory was balanced by a mighty energy diverted to the immediate purposes of the war. This "intellectual mobilization," however, with its regimentation of effort, smothered the individual expression which is necessary for creative thinking. There was, in effect, a widespread renunciation of intellectual independence. Since each party to the conflict set up as two contrasting political systems its own scheme of ideas and that of its opponents, the field of possible variation in individual opinion on any question was narrowed down to the right view and the wrong, and to take the latter was to be traitorous. Historians therefore became official propagandists and focused on the prevailing struggle their interpretation of the past; sociologists and philosophers adapted their theories to the compulsions of the moment; religious leaders rationalized their teachings; writers and painters harnessed their imaginations to the uses of persuasion.

This intellectual mobilization also conscripted social scientists into the administrative techniques of government, and here their efforts were at once more effective and eventually more significant for scholarship. Statisticians and economists were drawn freely into the fiscal and industrial services; political scientists were called on in administrative organization; psychologists, sociologists and social workers were

set to administer the problems of morale; jurists were assigned to smoothing out industrial friction. The administrative techniques which had been developed in the large business corporation, where effective action had to be combined with the representation of conflicting interests, were taken over in the business of war. Even in a country like the United States, where the rhetoric of democratic government was so compelling, the elected representatives of the people made way for the dollar-a-year businessmen and the corps of technical experts. In these activities social scientists had a chance to put whatever notions they had to the test of strenuous experience. There was scarcely a scholar who passed through these services who did not emerge, though a bit saddened perhaps, with an unaccustomed richness of realism added to his thinking.

He had been compelled in the course of his work to resolve ancient theoretical disputes in terms of imminent governmental policy, and to formulate techniques for transforming that policy into action. Which was a better method of financing war—loans or taxes? Should industry be confined to supplying the necessities of war and of the productive civil population or should business go on as usual? Should men in the essential industries be permitted to volunteer for military service or should they be required to remain at their civil posts? What measure of regulation was required to check the advance of war prices? The men making these decisions lived in a strikingly non-individualistic world, one where the crucial dichotomy was between the "essential" and the "non-essential," where everything superfluous was whittled away in the face of the primary needs and "priority" was accorded in terms of function rather than profit yield. In such a psychological setting it was not surprising that the theory and technique of the regulation of prices and qualities, of production and consumption, should undergo an unprecedented development. At the close of the war the public character of production in time of military emergency was universally recognized, but nowhere so clearly as

in the United States, supposedly the great stronghold of economic individualism.

The revolution in economic policy was only one of the adaptations made by the state to the unremitting demands of the military struggle. With both the Allies and the Central Powers the requirements of diplomatic strategy were to be found overriding established political traditions. Theories of political conduct were evolved which were sometimes deliberate posturings for effect and as often rationalizations of the position into which a nation had been hurried by the logic of events. Racial or linguistic nationalism, which had served the German Empire well in its formative period and which later fomented anarchy and war among the mixed peoples of the Balkans, had in Germany yielded ground long before the war to the doctrine of economic nationalism or rather supernationalism. The discarded theory was picked up by the Allies, in spite of the incongruities of their political structures, and under the propagandistic form of "the self-determination of peoples" served not only to animate the military or revolutionary efforts of Poland, Czechoslovakia, Yugoslavia, Rumania, but also to create unrest in Egypt, India and China. Again, the Allies, forced to contrive a bond of union and a plea for support, found it in resistance to the aggression of Germany. Military aggression, hitherto a policy within the permitted range of national initiative, became thereby a crime against the whole family of nations. To support this another premise was necessary—that of a collective international conscience. This rested necessarily on the postulate of international interdependence. There can be no doubt, however, that there was a reality in this conception. It was implicit in the war itself, which had drawn half the world directly into its prosecution and involved the rest of the world none the less fatally. The time honored distinction between neutral and belligerent was stripped of significance. War had become a world condition, and therewith the interdependence of nations an established fact.

The regimenting of the civil population to the necessities of warfare was a governmental problem of as pressing consequence as the revolutions in economic and political policy. Warfare on a world scale was not merely a matching of strictly military strengths; it was a confronting of every resource on both sides. Thus the long-standing distinction between the army and the civil population was blurred, since

the latter was now conceived as directly or indirectly an integral part of the general military organization. In consequence a host of military terms and adumbrating ideas were introduced into civil use. Of these by far the most important was "morale." In its original meaning the term had covered the unanalyzed complex of psychological factors that braced the rank and file of an army to the punishment of battle or the labors of prolonged marches or the miseries of a siege. In the World War it was extended first to munitions workers, then to industrial workers at large, and ultimately to the entire population. As in the army it had long been recognized that morale depends to a large extent on material conditions, such as abundant rations, suitable clothing, rainproof tents, so it was promptly recognized that the morale of the worker depends on similar conditions; the meeting of these requirements, either through direct government action, as in the housing programs of the several governments, or through regulation of wages and the prices of necessities, became an essential part of national military policy. So also care of the wives and children of soldiers at the front, felt to be required by military morale, led to increasing attention to the situation of the families of workers injured or invalided, as a requirement of civil morale.

These governmental techniques and policies, though not in themselves systematic ideas, represented the principal contribution made during the years of the war to the history of social scientific thought. Where the genius of a period is primarily administrative, as among the Romans, or in periods of stress when the necessity is for the effective execution of a program, the idea in action is the one that pushes forward ideological advance. The operations of the War Industries Board, the joint control of Allied shipping, the collective agreements entered into by labor, the manipulation of public opinion by publicity and propaganda, the studied maintenance of morale, the emergence of an international conscience—these were idea-movements of the first importance. Instead of having been evolved and systematically presented by individual thinkers they were the sum of the intellectual behavior of the community at a critical time. Actually of course they were rooted in the period preceding the war; when the emergency came, all the ideas and techniques which had been developed in business, politics and publicity were pooled, and the usual barriers which might have ob-

structed their acceptance, or their passage from one sphere of activity to another, were broken down.

As the conflict went on, its import for the life of society became clearer. The first burst of militant enthusiasm gave way to a disenchantment with the aims of both sides and a consciousness of the plight of the generation. The war exposed all the tensions and frictions attendant upon the operation of the prevailing economic and social scheme, and pointed the contrast between the degree of development of natural science and the haphazard control over social arrangements achieved by social science. The events and news of every successive day revealed a group of nation states competing for territory, colonies and markets, using all the resources of alliance making, secret diplomacy and armament races, each entrenched in its position by a traditional theory of sovereignty and impelled by an industrial system which made insistent demands for expansion. Men realized with dismay the racial animosities slumbering within the political entity, the aspirations of suppressed groups for autonomy, the jealousies and professional pride of military bureaucracies, the emotional hysteria which an idea or ideal could evoke in an entire population. The blundering and stupidity of officials, familiar enough in the diplomacy which had brought on the war, became overwhelming when they resulted in huge losses of life. Chemical, submarine and airplane warfare suggested the sinister possibilities of the application of science to the art of destruction. And meanwhile the waste of human and physical resources continued, carrying with it an increasing psychological tension of sacrifice and repression. Efforts at peace making met ludicrous failure; governments on both sides had gone too far into the conflict to be able to save face through any arrangement short of victory.

With the signing of the Armistice came a momentary outburst of optimism. It produced in America President Wilson's liberal basis for world reconstruction, and in England such notably creative expression as the program of the British Labour Party. But the disappointing character of a peace treaty which apparently opened a score of doors to new international disputes put an end to this mood. There followed a "war after the war" of indemnities, military occupation, diplomatic intrigue and commercial discriminations. Outside the Ver-

sailles scene elements were not lacking to add to the confusion: the crash of falling monarchies, the proletarian struggles everywhere, the hardening of militant communism in Russia, the violence of reactionary dictatorships in Italy, Hungary and Spain, the hysterias of radical-hunting, the rise of organizations like the Ku Klux in America and the secret military societies in Germany.

The economic confusion paralleled the political. Expansion and impoverishment in Europe gave finality to a process which had for some time been gathering force—a shift in the balance of economic power from Europe to America, with perhaps an accompanying shift of cultural influence as indicated in the phrase "the Americanization of Europe." Attempts to apportion Germany's indemnity and to adjust the payment of the inter-Allied debts involved the Powers in a sequence of bickering and bargaining which, while it cast an acrid doubt upon professions of altruism, was chiefly significant in revealing the financial instability of powerful states and their dependence on a delicate network of international economic relationships. Even the prosperity of the United States, proceeding from its amazingly developed industrialism, had certain disintegrating effects. It produced a heightened pace of economic activity which antiquated the approved economic virtues of industry, thrift and reliability, and conditioned a new set of virtues clustering chiefly around the rapid acquisition of wealth through speculation. In Europe, particularly on the continent, currency inflation had far reaching consequences for economic confusion. A radical redistribution of wealth put the bourgeois property holders in a helpless position; the rise of prices bore most heavily on the salaried and professional classes whose incomes remained fixed. With the value of money dropping further each day spending became the beginning of wisdom, and a general upheaval of values resulted from the erratic course of prices.

The mood of discouragement which followed the war was due in equal degree, however, to general psychological readjustments, based on factors less tangible than those responsible for the political and economic disturbances but no less compelling in their effect on the popular imagination. The cupidities displayed at the peace conferences, the publication of hitherto secret documents, the "now-it-can-be-told" attitude, revealed the actual motives of self-interest operating beneath the pretensions

of diplomacy. Millions of returning soldiers brought with them the memory of a struggle without rules and without chivalry, a Gehenna of misery and despair dealing death in a thousand inglorious shapes and leaving the survivors with their bodies mutilated and shattered—a contrast to the glowing adventure pictured by the civilian enthusiasts for the “healing war.” Although regulation and war taxes had curbed more or less effectively the cupidity of the profiteers, the close of the war nevertheless found in every country fortunes that had mushroomed up while the soldiers were perishing in the field and the industrial workers were straining with overtime and excessive speeding up. The accounting of war losses, hitherto glossed over in the interest of morale or borne stoically in the excitement of a successful offensive, now fell with crushing weight upon the spirit of the masses.

Revaluations so far reaching as these, when combined with the inevitable reaction from the tensions of the war period, could not fail to bring in their wake a general destruction of those traditional ties and sanctions upon which social organization depends. The widespread redistribution of wealth effected a social mobility which played havoc with caste. There was everywhere an increased restlessness, expressed in the exploitation of every means of travel, the preoccupation with amusements and the prevailing nervous distraction, especially of a neurotic post-war generation which found it impossible to unlearn its need for excitement. The mechanization of life, which had long been perceived by social observers, was extended even to the outlying populations of Europe, and in the industrial centers of America it reached a new perfection. There came with it a change in the institutional character of the home and the family. The increasing resort to divorce, the emergence of the companionate, the weakening of the tabus against birth control, the winning of suffrage, the approach of economic equality, combined to produce a new position for women in society. The rapidity of this change, which carried with it new conceptions of the conduct within the range of woman's dignity, was for many persons one of the most obvious manifestations of what was considered a relaxation of morality, a decay of religious faith, a broadening of the distance between the younger generation and its predecessors. As happens in all periods of transition, the impression of disorganization was probably intensified

by the censorious commentary from the adherents of the old order who were insensible to the reorientation toward new social standards and arrangements.

This disorganization confronted social science with its characteristic problems. Surrounding institutions and attitudes, however, are only the material with which it works; the color of its thinking and its philosophical cast are determined by the prevailing mood of the period.

In the face of the revelations which followed the Armistice the exalted mood of sacrifice and spirituality was not able to survive and a stern withdrawal from the benefit-of-the-doubt attitude was inevitable. The veil was lifted from the pretenses of the previous age of innocence. The generation after the war, in its unmitigated repudiation of idealism, found for a time no stopping place short of a derisive cynicism.

This disillusionment and its expression in a studied resolve not to be fooled came upon the community with so much force that it quickly colored all attitudes and captured all sections of society. Even the least sophisticated evidenced its influence in their suspicion of all “theories,” their trust in science and the certitude with which they placed their faith in “facts” and stressed the uniqueness of experience as the test of truth. Among the intellectuals themselves the most esteemed attitude was an anti-intellectualism which took particular delight in pillorying the academics. Wilson's idealism, as a possible new regime in politics, began to seem somewhat ludicrous, partly, perhaps, because it had been unsuccessful. Success was esteemed as the proof of merit, for tangible results were more highly valued than altruisms which depended on faith. Even in the pulpit religion came to be represented less as a worship and more as an adjustment to the conditions of modern life. A book representing the founder of the Christian religion as a business man and the contagion of his faith as the triumph of salesmanship received a popularity which proved its ideals eminently compatible with the public taste. The history which the layman preferred to read was that in which the force of ideals was discounted, and a book giving a basically economic interpretation of the growth of American civilization had an unprecedented sale in the United States. In fiction the mood was evidenced equally by the “hard-boiled” dialogue of Hemingway, which seemed to express so adequately the unyielding surface of

experience, and by the accumulation of a literature of escape in schools so far removed from each other as those of James Branch Cabell and the writers of mystery stories. Nowhere, however, was the complete capitulation to this mood shown so clearly as in the bludgeon strokes of the "debunking" school of biography, and in the enthusiasm with which the concept of bunk was received and applied to every possible situation. "Bunk" was the answer of the post-war generation to the inculcated "morale" of the war years.

An important result of this trend toward greater interest in actualities was the shifted emphasis in educational method. This realism was responsible in no small degree for the noticeable inclination to discard the old methods of inculcating formalized knowledge and to stimulate the pupil instead to make his own investigation, analysis and deduction. Other influences also had much to do with the change, such as a fear of the "goose-step" standardization effected by uniform educational methods and centralized control, and the formulae of the newer psychologies and philosophies. The result was to give educational theory a flexibility and experimental temper for which a parallel can be found only in the great age of educational advance—the eighteenth century. There was also a greatly increased interest in adult education, not only in organized classes, but in its other aspects as lectures, clubs, discussion groups. Attempts at the humanization of knowledge found a ready audience, and popular studies for the lay reader appeared in all branches of learning. An important factor in this desire for "culture" was the greater leisure and new social position of women, which gave them an increasingly important position in the intellectual life. Women came more and more to constitute the major portion of the public consuming literary and artistic productions.

The most insistent of the newer educational interests was psychology. As an elective in institutions of learning, as a subject at popular lectures and commercially managed schools, as a therapeutic technique in social case work as well as in one's own individual adjustments, and even as a topic of conversation it overshadowed every other "cultural" interest. This popularity derived somewhat from the war, with its exposition of abnormalities and its problems of shell shock; it was certainly the result also of the strenuous character of modern life which made necessary a technique of

adjustment. Inseparable from the reliance on psychology as a method was the interest in personality in the application of that method. This was in part merely an application toward one's self, one's neighbor and one's hero of that desire for ultimates which informed so completely the temper of the time. It was undoubtedly one of the factors in the biography boom, in which the gloriously dead, who had been formerly the concern only of the historians, were now subjected to a psycho-analytical scrutiny for the curious. The same influence was to be found in the novel, not alone in the absorption with sex but also in the emergence of the "stream of consciousness" method, which found its way even into historical narrative, as in Carl Becker's *Eve of the Revolution*.

This self-examination extended itself to an unprecedented interest in the character of the modern world and the immediate social environment. Spengler subjected western civilization to a pessimistic analysis in his *Untergang des Abendlandes*, and Keyserling in a more nostalgic vein expressed a lyrical admiration for the highly contrasting oriental way of life. This increased awareness of contemporary culture found particular expression in a widespread interest in the new industrialism and in the potentialities of science and the machine for effecting far reaching transformations in our culture. America and Germany especially—the first a new culture inviting definition, the other a defeated group seeking a new orientation—experienced an outburst of national introspection which yielded revealing analyses of their respective civilizations. In America H. L. Mencken and Sinclair Lewis found a wide audience for an unsparing and unflattering summary of American life which Robert and Helen Lynd in an inductive study of a typical community (*Middletown*) found to be not very wide of the mark. Another group, represented by Van Wyck Brooks, Lewis Mumford and Waldo Frank, sought to isolate the American essence with an eye to its enduring contribution to the cultural stream. This heroic and concerted effort to understand contemporary culture carried with it a conviction that scholarship must concern itself with immediate problems, and an enduring and vital art must do its work in the context of contemporary culture and draw its material from it.

The principal character of the abstract thought of this period was a growing sophisti-

cation, which represented an inclination toward skepticism of apparent conclusions and with it an increased subtlety and self-consciousness of approach. There had been a tendency in this direction for a good many years, as evidenced by the work of Poincaré and the non-Euclidian geometers, but in the years after the war it received an impetus which was due in no small degree to the congeniality of the prevalent intellectual disposition. Scholars showed their discontent with abstractions and *a priori* generalizations by their efforts toward a substantial realism in thinking, toward a greater immediacy between theory and the substance of theory. There was in all branches of science an increasing distrust of absolutism in thought, which found expression in a growing wariness of the "self-evidence" of axioms. The study of structural logic gave way to an experimental logic in which as much attention was paid to the authenticity of the premises as to the validity of the processes of reasoning. The researches of Einstein in physics made explicit the principle of the relativity of phenomena which was at the same time being evolved in analogous forms in other departments of thought. This theory, when applied to social science, threw the emphasis on the individual or the single event as the term of reference and effected a sense of the complexity of a problem and of social relationships which made William James' concept of a "multiverse" conform admirably to the intellectual temper of this period. The war had done much to prepare the way for such a conception by impressing upon people's minds the breadth of the horizon and the complexity and divergence of world politics, attitudes, institutions. In art particularly this had the effect of adding to the schools of realism an antithetical group which was doubtful as to whether the most effective statement of reality cannot be attained more accurately by indirection and suggestion rather than by naturalistic representation. Simplicity and unity were everywhere regarded with a suspicion that arose from a belief that if one pushed back far enough one found always the simple disintegrating into the complex. This sense of complexity was dangerous for many in that it often defeated impulses toward constructive effort.

A further issue of the widespread convictions of complexity was more limited in its reception but affords what may possibly be an indication of the trend of scholarly thought in the future. There was explicit recognition by many scien-

tists that any one of a series of divergent conceptions of the universe might be equally tenable, and the realization of this led certain thinkers to a skepticism of the value of the scientific method as it had been developed and crystallized. There were some who even expressed a discouraged sense of the futility of science. This attitude was distinctly contrary to popular faith in science as a panacea, but it was nevertheless a result to be expected as scientific thinking developed to such an extent that it defeated its own purposes.

In their attempt to escape the simplicity of unitary answers and yet avoid metaphysics, philosophers and social scientists were driven to a set of beliefs and techniques which were at once less demanding and more satisfying. They had resort to a quantitative objectivity which left little to judgment except the measurability of the phenomena and little to speculation except the interpretation of the results. Wherever theories had already been advanced and become tenacious they were subjected to a verification proceeding inductively and quantitatively. The dominant philosophy of the period was a pragmatism which ignored innate values and concerned itself with the attainable good, and the dominant psychology an experimental behaviorism which took nothing for granted except the primary significance of overt behavior. The extent of these attitudes may be measured by the impact of behaviorism upon method in the social sciences and upon education, and the ramifications of pragmatism in case law, pluralistic political theory, labor policy and social work, in institutional economics and social history.

All of these philosophical and scientific attitudes were merely the more recent accretions to an intellectual heritage as old as western civilization. Many of the older attitudes maintained considerable vitality and constituted the corpus upon which new elements were grafted. This confronting of the inertia of philosophic systems with the mobile and various currents of mood, belief and conduct in the general disorganization of the post-war period offers an approach to the understanding of the chaotic nature of the period. Every thinker carried the past in his brain; but he wrote at a time when a succession of new attitudes strove for survival, false starts and tentatives played themselves out or were deflected from their intention, bursts of feeling and eddies of belief made something of a stir before they were lost in the more

permanent currents of thought. Attitudes based entirely on the tensions of the war lost after a time their identity. Temporary flurries of extreme idealism and extreme disillusionment were equally fruitless of permanent results. Intellectually the period was one of startling contrasts and juxtapositions, one in which nothing from the past was abandoned, much was started in the heightened atmosphere of intellectual excitement and social transition, and very little was brought to completion. This gives the period a richness and variety which are at once a warrant of its fertility and vigor and a warning against summary analysis, for in its complexity can be found substantiation for almost any formulation of trends.

II. PSYCHOLOGY. The social sciences were probably more profoundly affected by the development and diffusion of psychological doctrine than by any other single influence that touched them. Psychology's penetration of social studies was already in progress in the late decades before the war. Wundt, the dominant figure in late nineteenth century physiological psychology, had crowned his work with an impressive contribution to sociology, and if his influence on the sociological system builders remained negligible it did at least operate to encourage the trend toward social interpretations among the psychologists.

From the opposite pole of mechanistic economic theory sporadic flashes of psychological insight began to appear. From the time of Jevons orthodox economic theory had been increasingly dominated by the impulse to translate the whole problem of value into "subjective" terms. Values were derived from wants, desires, and these psychological phenomena were generalized to homogeneity with no relevant differences that could not be manipulated by quantitative measurement. This subjective psychology had been vigorously challenged by the heterodox theorists of the time: Sombart, who found it necessary to draw upon a whole complex of psychological motives to account even for the thirst for indefinite enrichment; Veblen, who sought not only to break up the rigidities of subjective theory by an appeal to the motives and instincts of contemporary scientific psychology, but even more to establish a psychological basis for the Marxian theory of class consciousness. Veblen and his followers, Hoxie and Stuart, levied most heavily upon the theory of instinct presented by McDougall in his *Social Psychology*, published

in 1908. The same work exerted a marked influence upon sociological thought, operating toward the weakening of ambitious systems of sociology and the concentration upon problems of individual motivation.

Within the field of psychology itself several new leads having a significant bearing on the social sciences were opening up. The most important of these were the new approach to abnormal psychology under the leadership of Freud, the study of the "conditioned reflex" initiated by Pavlov, the studies of differences in intelligence inaugurated by Binet, and the study of organic groupings of perceptions, which received its impetus from the work of Stumpf and Husserl and was developed into a definite theory of Gestalt or configurationism at the hands of Köhler and Koffka. In each case the immediate application was limited at first to a narrow range of problems: psychoanalysis to psychotherapy; the study of the conditioned reflex to the interpretation of certain anomalies of behavior; the Binet tests to the detection of feeble-mindedness.

Setting out with a study of neuroses and other psychological abnormalities, psychoanalysis had effectively established the existence of a range of motives not appearing in the consciousness of the patient, but nevertheless determining his behavior. Not only was the "unconscious" capable of motivating action that otherwise would have to be explained as purely capricious; it was also capable of controlling the conscious motives. The old distinction between "real" and "professed" motives, with its implications as to good and bad faith, gave way in the psychoanalytic psychology to a distinction between unconscious and conscious motives, with implications of personal irresponsibility.

Within the psychoanalytic group itself grave schisms arose over the anatomy of the "unconscious." Of these one of the earliest was headed by Alfred Adler, who broke away from a loose alliance with Freud and set about developing the implications for psychotherapy and education of an assumed universal striving for superiority. A later schism was led by Jung, in whose system congenital differences in type count heavily alongside of the submerged data originating in conscious experience. A third important schism was that of Rank, with its emphasis upon traumatic influences on behavior. These differences have had no significant repercussions in the social sciences. The social scientist, and the psychiatrist as well, have drawn eclectically

from the several schools, following the pragmatic principle that any psychoanalytic tool is good as long as it works.

Prior to the war the application of psychoanalysis to psychopathology was extremely restricted. The intolerable terrors and hardships of the fighting revealed the prevalence of psychological abnormalities in the rank and file drawn to the front. "Shell shock," a phenomenon not unknown in earlier wars but disposed of naïvely as "cowardice," became so common as to demand hospitalization and treatment like any physical wound. The services of psychotherapists were requisitioned by all the warring nations, and the methods of psychoanalysis were found useful. Naturally the war-time recognition of the wide distribution of psychical abnormalities was carried over into the reconstruction period. A host of behavior abnormalities formerly treated as vices or crimes came to be regarded as manifestations of psychopathology, demanding treatment rather than repression, prophylaxis rather than exemplary punishment. Psychoanalytic methods consequently gained wide currency not only in social work and in penology but in education, where they formed a main constituent in the increasingly popular courses on "mental hygiene."

Far subtler, but probably more potent, was the influence of psychoanalytic study upon the intellectual temper of the post-war period. The enthroning of the "unconscious" as the dominant factor in behavior was eagerly applauded by a generation in revolt against "bunk." It became possible to set up the concept of unconscious propaganda alongside of the less convinced and hence less effective conscious propaganda, as a resistance to every kind of social compulsion. Noble sentiments operating oppressively might be explained, not as formerly in terms of hypocrisy, but in terms of unconscious self-seeking motives. Thus the unconscious became a potent means of personal "liberation," to the horror of the conservative, who was becoming aware only gradually that the emphasis of psychoanalysis upon the "libido" was the least revolutionary aspect of the tendency.

The hold that psychoanalysis had achieved for itself was obviously reflected in the literature of the period, as for example in the fiction of Joyce and Lawrence, in the dramas of O'Neill and above all in biography. Freud himself had set the pace in his interpretation of Leonardo. A host of biographers followed after, scrutinizing the records of great men of all the ages for

indications of their "real" motives, that is, their unconscious, often their meaner, more selfish motives. The economic interpretations of the pre-war generation had made a mere figurehead of the "great man." The post-war spirit infused into the great man a superior reality, a more representative quality, but more representative of the unconscious egoistic strivings of his time.

For almost a decade the discoveries of Pavlov led a half animate existence in the laboratories of the animal psychologists. Among the other psychologists, even in Europe, they never exerted more than a mediocre influence. In America they were taken over by Watson, supplied with an effective name, behaviorism, and launched with the modest claims of a new, completely objective method of studying psychological phenomena. By the close of the war Watson had already trained a considerable number of able disciples who were rapidly building up a behavioristic literature. With the publication in 1919 of *Psychology, from the Standpoint of a Behaviorist* Watson undertook to maintain the omniscience of the behavioristic method in the handling of all psychological problems of a strictly scientific character.

For the social sciences the importance of behaviorism was partly methodological, since it was seized upon by many social scientists as a justification for their preference for concrete studies and their aversion to the large generalizations of the preceding generation. Its chief bearings, however, were upon education and family relations. In maintaining that personal character and ability are the products of "conditioning," Watson was led to concentrate his attention upon the earliest years of life. The pre-school child became the most important object of educational effort. And since the pre-school child is mainly subject to conditionings originating in his immediate family environment, a first task of educational policy was an attempted revision of family institutions, in order to create a more rational milieu for the development of character.

Like psychoanalysis, behaviorism operated to dissolve the sense of personal responsibility. A forger, a perjurer, a thief had been improperly "conditioned" in childhood. Their cases demanded "reconditioning," and the brute repression effected by criminal law should eventually give way to a rational technique of reconditioning. The doctrine fitted admirably into the temper of the times and attained a temporary currency far beyond the academic world

Both psychoanalysis and behaviorism, while releasing the individual from the burden of personal responsibility, left an open way for social perfectionism. Both have inherent leanings toward social action. This is not true of the psychological implications of endocrinology, which for a brief space appeared over the intellectual horizon only to sink back into pure physiology. What one really was, according to this doctrine, was determined by the constitution and functioning of his endocrine glands. Glandular unbalance, most often irremediable, was responsible for grave aberrations from normal standards; a happy constitution of the glands laid the true basis for achievement. Endocrinological psychology attained a modest place in psychiatry, criminology and in social work. Beyond these technical fields its influence promptly disappeared.

Far greater importance for the social sciences must be assigned to Binet and the "intelligence tests" that have grown out of his work. While the theory and practise of intelligence testing were already well developed before the war, they received in America an enormous access of popular interest from their wholesale application to the examination of recruits, with a view to the selection of those fitted by character for promotion. After the war they played an increasingly important part in American educational administration and were also applied sporadically in the selection of industrial personnel. Their underlying assumption of congenital differences in intelligence gained almost universal currency in America and exerted an influence by no means negligible upon political policy—notably in immigration legislation and the so-called "eugenics laws" of the states.

For social science the most important bearing of the intelligence tests has to do with democratic theory. That theory reached its highest point in the period of environmentalism of the late eighteenth and early nineteenth centuries. Those who accept as valid the theories of the Binet school must inevitably conclude that the traditional democratic theory is unworkable. A large—and according to the eugenicists, increasing—fraction of the population is congenitally unfitted for political responsibility; and only a minute fraction is actually capable of a high order of political activity. It is worth noting that the theory of the intelligence tests, while widely accepted by educators, administrators and the conservative intelligentsia, was indignantly repudiated by the restless and dis-

illusioned "younger generation." By them it was considered reactionary, an "unconscious" defense of the old order of inequality and oppression.

One final tendency in psychology needs to be noted, that of the Gestalt or configurationist school. Its fundamental conception, that organic groups of facts are perceived as unities, not pieced together in the mind fact by fact, has been pressed into a bearing on social theory as a truer statement of the position of the individual in the group. It has also begun to penetrate educational theory. But as a late comer its influence upon the social sciences in the period under review is modest.

No summary of the definable influences of psychology can give an adequate account of its real importance for the social sciences in the post-war period. Especially in the later part of the period psychology was "in the air." No social scientist not altogether impervious to the general movement of thought could fail to pay it tribute in the laying out of his problem, in his critical judgment of his own methods. No scheme of social reform could be launched without close survey from the "psychological approach."

III. GEOGRAPHY. In so far as geography is allied with the social studies it was until the twentieth century scarcely more than a subsidiary interest and a point of view on the part of historians or social theorists. In the early decades of the new century, however, there was an extension in the scope of geography and also an increase in its effect on the methodology of the other sciences. The shifted emphasis among geographers and the increased interest on the part of other scholars were stimulated by factors from many different directions: the increased interdependence between one part of the world and another; the development of anthropology and the awakened interest in the hypothesis of races; the general trend in all branches of study away from arid description and in the direction of an analysis of genesis, causes, interrelations, results. The World War brought a new necessity for knowledge concerning remote places and quickened the perennial curiosity about them: it upset old notions of national arrangements and brought to the focus of attention regions hitherto disregarded. It forced a universal recognition of the bearing of topography upon military strategy; the diplomacy of the war period, with its anticipations of the redrawing of bound-

aries in terms of military defense, nationality, economic resources, accessibility to trade routes, elevated the map to the rank of a first principle of higher politics. At the peace conference every delegation had its corps of trained geographers to bolster up its territorial claims. An improved art of cartography offered a technique for managing new materials and made possible a more analytic as well as a more concrete development of the science.

It was in the development of human geography, however, that the science began to achieve a directed interest in cultural problems. Geography had always contained something of ecology. In fact environmental determinism, which had flashed as a bright bubble to a good many social theorists, at times claimed the energies of this science too. Environmentalism involved the study of all of human culture in relation to physical phenomena. When the belief was discarded that the physical world directly determined cultural forms, the realization remained that there was nevertheless a relation which geography could claim as its basis of study. The study of human geography was the result, inaugurated by Ratzel with the publication of his *Anthropogeographie* (1882-91) and carried on by Ellen Semple, Elisée Reclus, Vidal de la Blache, Jean Brunhes. In the process of its development certain aspects of man's activity became particularly emphasized and were separated as distinct divisions within the science—commercial, political, economic geography. From this extension of interest the other social sciences derived less of actual consequence than did geography itself. This very impetus in its own domain, however, resulted in bringing the subject closer to the foreground in social study. History, in particular, began to pay greater attention to the background of climate, soil and physical environment.

As the content of the science increased, geographers came to feel the necessity for a specific basis of study before their results could become anything more than mere preliminaries to future collation. Their method of dealing with new materials had remained for the most part undirected and inchoate and left the science in a position of indecision as to its purpose, and confusion as to its achievements. It was largely because of this need for a unity of approach, similar to the method of experimentation in the natural sciences, that the concept of regionalism was adopted. The content of geography remained the same but its method of study was

adapted to an intellectual milieu which produced the case method, institutional economics, behaviorism, political pluralism and stream of consciousness.

The thesis of regional geography is that a more provocative means of studying man in relation to his environment is to concentrate attention not on the reciprocity between them, in terms of either physical or cultural phenomena, but on a specified area in which the works of man and the works of nature, of the past as well as the future, will be studied with as great a degree of thoroughness as possible, letting the conclusions shape themselves. The ideal of objectivity of course is blurred by human conditioning, but regional geography stands for a method of investigation which is likely to prove of value in the orientation of the science. It resulted, particularly in France, in a host of localized studies which integrated the culture of a community with unaccustomed clarity and suggested provocative possibilities for social control.

The tendency of geography to turn toward regional studies raises afresh the question of its province and its unity. As the study of geography moves from the general to the specific in its development from physiography to an analysis of culture areas, it deals with increasingly complicated problems in which the influence of physical factors alone is a less and less sufficient explanation. The location of industries, the character of social organization and institutions, may be influenced by natural conditions, but there are so many further considerations that must be taken into account in reducing to terms the culture of an area that physical facts alone can serve the geographer only as a point of departure. In fact as he ceases to be a physiographer he comes closer and closer to the craft of the anthropologist, the historian, the sociologist, the political scientist, the economist. In this regard geography represents a close analogy to history, which is also necessarily eclectic. History describes its material in time with some regard to place; geography works on the basis of place with some regard to time. They must both consider the entire cultural structure. This complexity, which increases as geography becomes more critical of its purposes and methods, renders it, like anthropology, an exercise in synthesis. In so far as geography is in itself a social science it must be an analysis of the relationship between the life of the community and the natural and the cultural landscape; in so far

as it affects the work of the other social sciences its influence must still be confined to its method of approach and its emphasis on the possible effect of physical surroundings.

IV. ANTHROPOLOGY. In the early decades of the twentieth century anthropology passed through its novitiate and attained a considerable maturity. At the beginning of the century the German folk psychologists, the French pre-aistorians and sociologists, the American field investigators attached to museums and government departments, the British school whose halcyon grace of writing has made it classical, were quarrying rich veins of material and erecting theoretical structures which had to be critically overhauled. The scattered ethnographic literature, much of it as haphazard in method as the group of travelers' tales whose tradition reaches back to Herodotus, gave way to arduous field studies whose objectives and methods were mapped out at the very start. The divergent tendencies and pioneer tentatives of the formative years began to be integrated into a more unified sweep of research and interpretation which made anthropology the study *par excellence of culture*.

No study suffers so decisive a development in the course of a few decades unless the explanation is deeply rooted in the complex of relevant influences that constitutes its setting. Methodologically the study was an outgrowth of the desire of social scientists in the latter nineteenth century for some sort of comparative or historical method which would afford relief from their self-contained systems. Scholars impatient at being restricted to the study of occidental communities as revealed in written records sought replenishment by breaking into alien and uncharted reaches of intellectual experience. Early interests in prehistory linked anthropologists with archaeology, and the physical anthropologists were absorbed with biology and statistics. But the principal impetus came when occidentals were brought into contact with the primitive cultures of Africa and Asia as a result of imperialist expansion and missionary zeal. The arts of life "in darkest Africa" seemed to offer fresh and luminous comparisons with our own culture. On such subjects as religion, sex and race, which received emphasis in the writings of Tylor, Frazer, Robertson Smith and the other early writers, hope ran high that anthropology would provide the final word. It was a not impossible surmise that if bedrock was to

be found anywhere in the search for the essential in social behavior one might think to find it in the uncontaminated impulses of the "savage" and the "primitive." A "great society" bewildered by its own mechanisms and weighted down by its accretions was fertile soil for the cult of primitivism. Moreover to scholars seeking to study human society not piecemeal but as a totality the small primitive community offered the entire range of cultural activities in a compass small enough to be envisaged by a single investigator; and it had the additional merit of being so alien to him that he could hope to approach it with the detachment which stamps the exact science. Field studies undertaken in such a spirit accumulated so rapidly as to be increasingly unmanageable by the conceptual apparatus of an earlier order.

In this context anthropology broadened, lost some of its crotchets, became subtilized, reached for maturity. It did not, however, in the process of becoming a cultural study, abandon its earlier interest in archaeology and physical anthropology, but rather attempted to fit them to the purposes of the newer interests. Archaeology, always of service in uncovering skeletal remains and artifacts and thus piecing out the broad outlines of man's history, received added meaning as an instrument in plotting the geographical distribution and time sequence of culture traits which the diffusionist controversy made important. Kidder and Nelson in the southwestern United States, Uhle in Peru, Joyce and Spinden in Mexico and Central America, archaeologists in Egypt and Mesopotamia, with the aid of elaborate and scientific equipment and considerable financial support, utilizing the developments in the art of photography and even in aeronautics, applied themselves with substantial success to the task of discovery and historical reconstruction.

Physical anthropology, which concerned itself chiefly with the development and distribution of racial types, achieved a more stable if greatly moderated position in the new alignment of anthropological interests. Its early dominance in the science was due in no small degree to the fact that its data lent themselves most readily to metrical and statistical study and presented thereby an appearance of objectivity. The investigation of the racial history of man in its sequence from the anthropoid apes through the Heidelberg and Neanderthal specimens to the contemporary distribution of racial types required for adequate study a rigorous technique

of exact measurement; by 1914, as a glance through Rudolf Martin's *Lehrbuch der Anthropologie* will show, this technique had attained a high degree of complexity. At times it tended to lose sight of its instrumental character; at times it was deflected from its primary intention into arid excursions and unscientific uses. But in general the later work in this field shed increasing light on the origin of contemporary racial types, the determination of their ancient habitats and the course of their migrations, the intensification of their hereditary traits in isolation and their modification under new conditions of physical and social environment.

The postulates of such a study being those mainly deriving from Darwinism—evolution through heredity, environment, selection and mutation—its fortunes varied with the refinement of these postulates and the fluctuations in their scholarly acceptance. The emphasis on the purely biological influences, deriving from Galton and Pearson, had to be qualified; scholars came to recognize that “man in the very fact of culture transcends his biological equipment” and became aware of the difficulty of separating the somatic from the social. There was throughout an extension of the base on which the study rests. A discipline which began with the primary intention of ascertaining the antiquity of man and tracing his natural history broadened into a study of the biological factors underlying human phenomena.

Outside the field of scholarship a set of events occurred to heighten the tension of the surrounding emotional atmosphere within which scholarship is compelled to work. The growing consciousness of nationality before the war, the hatreds arising from the war, the problems raised by immigration and by diverse racial groups contained within political boundaries, released a poisonous cloud of invidious racial claims, accusations and refutations which found expression in a pseudo-anthropological literature as well as in popular acceptance. The controversy precipitated the demand for a trial-balance of the conclusions of anthropological science. The crucial question was of course the correlation of physical race characteristics with different degrees of cultural achievement. The answer of the earlier race theorists would have contained much more certitude than did the prevailing critical attitude of this period. Although some students did not abandon the hope of finding physical criteria for races, there was an increasing volume of scholarly opinion

which held that the concept of race is elusive, that any so-called race may contain many subdivisions and a wide range of variation, that it is difficult to define the physical criteria of a race, and finally that differences in the civilization of two racial groups can be explained historically without introducing any assumptions of biological superiority.

Closely related to this episode, in its bearing on the existence of a “talented race” on whom mankind is presumed to draw heavily for cultural advance, was the controversy over the diffusion as against the independent origin of cultural traits. Drawing into its orbit every important school of thought this became the moot question of modern anthropology; its insistent claims for attention gave this period a highly methodological color and tended to divert scholarly effort from more fertile channels.

The chief impulse to the controversy came from the reaction of modern critical anthropologists against the classical school of Morgan, Tylor and Frazer, whose concern had been to trace the history of culture in an evolutionary unilinear progression, as if by some preconstructed escalator mankind had mounted to its present level of Christianity, monogamy and occidental science. Deeply under the influence of Darwin and Spencer they mapped out a succession of stages through which each culture was likely to pass in its institutional development. Modern critics of this theory, taking as a typical example the evolution of marriage, pointed out the fallacy of premising a sequence of promiscuity, group marriage, polygyny and monogamy. But the chief controversy raged over a corollary of evolutionism. If, as Tylor held, institutions develop “in a series substantially uniform over the globe,” this would be possible only on the assumption of the psychic unity of mankind. And this in turn leads to the position that cultural advances need never be borrowed by one community from another, but are evolved independently.

In the full swing of the reaction against this position German and English theorists attempted to explain the building of cultures by the concept of diffusion from one or several centers. Graebner, followed by Schmidt and Koppers, set up a scheme of three primary *Kulturkreise* corresponding to divergent types of economic organization. G. Elliot Smith and W. J. Perry went even further and contended for a monistic pan-Egyptian origin of culture. Both of these diffusionist schools denied the

possibility of independent invention in explaining cultural parallelisms. The simplicity of the antithesis and the sensational character of the pan-Egyptian hypothesis undoubtedly counted for much in the attractiveness of the dispute, but the controversy itself is an earnest of the genuine intent in modern anthropology to penetrate to the origin of culture and the nature of the cultural process.

The prevailing tone of anthropological theory after the war was critical. The early formative period had produced hypotheses which suffered considerably from the exuberance attendant on the launching of a new science, but whose vitality was evidenced to some degree by the later concern to disprove and qualify them. One has only to mention such concepts as animism, mana, tabu, totem, folkway, matriarchate, exogamy, domestication, pre-logical mentality, and each of the terms, in addition to whatever specific meaning it has for us, carries along a penumbra of polemic discussion and intellectual possibilities that betokens the creative idea. With so rich a start the next stage was inevitably one of critical concentration. Tylor's concept of animism, Durkheim's theories of primitive religion and the role of the group, the whole conception of the kinship scheme, the force of tabu, the rigidity and compulsion of custom, the nature of primitive mentality and the stages of primitive economic life—all of these concepts were unsparingly subjected to reconsideration. Marett, Malinowski, Radcliffe-Brown, Thurnwald, Vierkandt, Boas, Lowie, Kroeber, Goldenweiser, Sapir, Radin, Benedict and Wissler, while varying widely in the character of their emphases and the nature of their conclusions, were all animated by an essentially similar critical intent.

This theoretical sobriety was nourished largely on the exacting influences of the new mass of descriptive literature. There had been in the earlier period an ample number of missionary reports, of which the seventy-three volumes of the *Jesuit Relations* in the field of the American Indian will serve as an instance, and chance descriptions by travelers. These were followed by monographs from scholars who came to their task with more zeal and literary flourish than purposive equipment. It was largely researches such as these that formed the basis of works of synthesis like Frazer's *Golden Bough*, and the validity of the resultant theory derived rather from the cumulative impressive-

ness of a monumental mass of material than from the authenticity of the individual sources. The closer grappling with realities that was the dominant note of the critical period finally sent the theoretical scholars themselves into the field. There followed an output of excellent monographs in the best of which industry and scientific equipment were united with a vivid insight into the community studied. Seligman's *The Melanesians of British New Guinea* and *The Veddas*, Rivers' *The History of Melanesian Society*, Westermarck's *Marriage Ceremonies in Morocco*, Spencer and Gillin's work on the Central Australians, all appeared between 1910 and the outbreak of the war. The Jesup Expedition to Alaska organized by Franz Boas and the Cambridge Expedition to Australia organized by A. C. Haddon were outstanding large scale cooperative attempts at field work. The work of Boas' students among the American Indians and in other regions and Malinowski's series of monographs on the Trobriand Islands (especially his *Argonauts of the Western Pacific*, 1922, and *The Sexual Life of Savages in North-western Melanesia*, 1929) show that the new and more regimented methods for conducting a field trip had not destroyed the ethnographer's gift of imaginative sympathy.

These local studies and the accumulated geographical-historical material which had to be put in order after the diffusionist controversy and plotted for the distribution of anatomical and culture traits tended to make the anthropologist map-conscious. He charted the world for purposes of intensive study, so that to be a specialist meant to know everything about a part of the map. The rapid disappearance of primitive races through conquest, disease, labor exploitation and cultural contacts made the immediate accomplishment of this task imperative.

A belief prevalent among anthropologists regarded the field trip as the mainstay of anthropological method and credited the body of literature deriving from it as being the indispensable basis of all induction and inductive verification. To establish a basis for comparison of data a roughly uniform conceptual technique was worked out which divided the cultural life of the community into certain principal activities and studies each in relation to the others. The language, the social organization, the religion, the knowledge, the technology, the economic life, the law and government, the sexual and aesthetic life of the community, as well as the anatomical and physiological aspects of the

natives, were subjected to a curious and detached scrutiny by a kindly, bespectacled white man, heavily swathed in mosquito netting and dosed with quinine. Elaborate and voluminous notebooks and photographic and moving picture cameras helped to make permanent and accurate the impressions of the moment. The field study in its present highly developed form is confederate with the critical method, since its principal use is to subject the hypothetical flights of expansive theorists to verification and lay the basis for a new theoretical synthesis.

When such a synthesis comes it will in all probability attempt to encompass the origin and history of culture. The principal positive theoretical position of the early decades of the twentieth century was the glorification of culture. The word loomed more important than any other in the literature and in the consciousness of anthropologists. Culture traits, culture complexes, culture types, culture centers, culture areas, culture circles, culture patterns, culture migrations, cultural convergence, cultural diffusion—these segments and variants point to an attempt to grapple rigorously with an elusive and fluid concept and suggest incidentally the richness of such a concept. Concern was rife over the birth of culture, its growth and wanderings and contacts, its matings and fertilizations, its maturity and decay. In direct proportion to their impatience with the classical tradition anthropologists became the anatomists and biographers of culture. Taking its point of departure from the diffusionist controversy, nourished by the schools of geographical distribution and historical reconstruction but not limited to them, the idea became pervasive that the proper study of the cultural anthropologist is culture. As a broadening influence and as an integrative force it did more than any other single fact to give anthropology its recent character. Whatever the differences in specific doctrines and techniques between the science in this and in the previous period, the principal change was this period's complete absorption with culture.

This common concern with culture has made the question of the division of anthropologists into schools of no supreme importance. The principal line of cleavage into schools has already been discussed—that centering around the issue of diffusionism. But the more formal and recognized division into schools runs rather in terms of the method and interest which the

particular anthropologist used in approaching his data. Thus a psychological school can be traced, dating from Wundt and the other German folk psychologists. This approach had fortunes varying of course with the stability of the developments within the field of psychology, but the latter soon demonstrated how indispensable it is in the study of the contact of cultures and the transmission of culture traits. Vierkandt, Thurnwald, Van Gennep, Goldenweiser, Sapir and Lowie were deeply influenced by such an approach and made some strides toward a psychological approach in the wide sense of seeking an insight into the spirit of other cultures. Earlier anthropology had made out the individual as completely submerged by the group. Schmidt, Marett, Malinowski, Boas and Radin used the psychology of individual differences effectively in restoring the balance between the compulsion of the group on the individual and the influence of the talented individual on the process of culture. A crude individual psychology was used by Lévy-Bruhl in describing the primitive mind as pre-logical (*Les fonctions mentales dans les sociétés inférieures*, 1910). Even the psychoanalytic approach was used, first by Rivers in his work on dreams and then by Seligman in his recording of primitive dreams. Malinowski's work on the psychological basis of sexual beliefs and kinship systems afforded considerable insight into the rationale of social organization. The sociological approach dates from Robertson Smith, Durkheim and such of the latter's followers as Mauss, Hubert and the *Année sociologique* group. In British anthropology Malinowski and Radcliffe-Brown inaugurated a functional school which, whatever its future stability, will be of service in calling attention to the necessity of studying an institution in relation to the essential role it plays in the community. Such an approach, if it could be made persuasive for colonial administrators, imperial statesmen and missionaries, might retard the ruthless process of the destruction of those native institutions which, in an occidental context, seem purposeless. The school which had the weightiest influence during the later years of this period was the historical school—mainly American—under the leadership of Boas. It was in the forefront of the new critical attitude in anthropological theory, with its emphasis on meticulous monographic study, unyielding critical austerity and an instrumentalist use of historical and geographical material.

Such a classification of schools is of little

value except to indicate that in the contacts with the other social sciences that have attended its development anthropology has been affected by their viewpoints. Through one approach or another the positive theoretical work of cultural anthropology went on—the study of the nature of primitive institutional life. Rivers (*Social Organization*, 1924), Lowie (*Primitive Society*, 1920), Malinowski, Thurnwald and Radcliffe-Brown in the intricate yet central problem of social organization, with sanity and insight dealt with kinship systems and group units; Lowie (*The Origin of the State*, 1927) penetratingly demonstrated the existence of territorial political organization even in those primitive units which seem most amorphous and anarchic; Malinowski (*Crime and Custom in Savage Society*, 1926) showed that among the primitives as among us law and custom are disobeyed as well as obeyed, and that the intricate pattern of individual impulses and group compulsions can in no society be reduced to a formula; Radin (*Primitive Man as Philosopher*, 1927) and Boas (*Primitive Art*, 1927) portrayed in the aesthetic realm too a process of the creative imagination that differs in no essentials from our own; the trend in religion (Lowie, Marett, Benedict) was to attenuate our traditional condescension toward the superstitions and irrationalities of the savage; Sapir (*Language*, 1921) traced the historical and psychological factors underlying language forms; Malinowski ("The Primitive Economics of the Trobriand Islands" in *Economic Journal*, 1921, vol. xxxi, 1-16) and Firth (*Primitive Economics of the New Zealand Maori*, 1928) showed that the economic activities of a primitive community, though they appear in the light of our own standards to be whimsically motivated and erratically directed, are dynamically linked with the social organization of the community and the psychological heritage of the natives.

More than in any positive dissemination of anthropological concepts, methods and literature, the outstanding significance of anthropology for the social studies in the period under review lies in what one student has called "the anthropological attitude." To be sure, the creation by anthropology of the concept of culture and its decisive influence on the other social studies, notably history and sociology, is of first rate importance. So also is the light that anthropology has cast on the problems of social organization. But more enduring than a theory is a way of thinking. And the anthropologist's way

of thinking has reached beyond his formal contacts with the other social studies and, like psychoanalysis and relativity, has entered into the main stream of twentieth century thought.

What this way of thinking needs a roundabout explanation and even then can only be adumbrated. Our own modern institutions are encumbered and entangled with their historic accretions and so self-evident to us that the clear outlines of their nature and purport are blurred. So we seek the primitive instance and think to find there the answer to our queries concerning the nature of institutional life. We expect with a certain naïveté to find there the essential disentangled from the accidental, whether it be the nature of law, the origin of the state, the psychology of sex, the essence of religion, the destiny of the individual life. Our unconscious premise is that the primitive community is a sort of laboratory or a vacuum test tube in which we can reduce all extraneous elements to a minimum and keep our eye on the main intent of the chemical reaction.

We may of course be defeated in our expectation. We may find that primitive life, though in a different way, is as complex as ours, and that what we thought to be the essence of an institution is only the result of the historical accidents of the primitive community itself. Imbedded in its own context the institution may still elude us. Thus after a half century of the anthropological approach to religion inaugurated by Robertson Smith we are possibly as far as we were from an understanding of the nature of religious experience. But such an approach always heightens the metabolism of our minds and breaks down our parochialisms.

In this dislocatory effect lies the chief intellectual value of the anthropological attitude. It views culture with a detachment that comes, not as the scientist seeks to attain it, through a heroic asceticism and effort at concentration, but with a certain slyness and indirection. The strangeness of the contrast between our way of life and the savages' surprises the student into a state of detachment. We always tend to view an eccentricity as from the outside. And in the reflex we are surprised into a similarly detached view of our own culture, seeing it not as endowed with an unyielding and inherent place in the scheme of things, but as mutable and merely a variant. The principal application therefore of anthropology to modern life has so far come not through the attack direct, but by way of a devious and unexpected illumination.

V. SOCIOLOGY AND SOCIAL WORK.

The grandiose projects for a unified science of society launched by the system builders of the late nineteenth and the early twentieth centuries had already begun to lose credit in the last decade before the war. On the one hand invading formulations from other disciplines occupied successfully much of the ground of sociological theory: anthropological formulations (Vierkandt, Durkheim); philosophical (Max Scheler, Jerusalem); economic (Weber, Sombart); historical (Troeltsch, Salomon); geographic (Le Play, Patrick Geddes). On the other hand the professed sociologists themselves turned away from central problems to special studies in social policy such as criminology, problems of education, population, race. An important colony of the older sociology, "charities" and the allied problems of poverty, had declared its independence and set up a system and techniques of its own under the rubric of social work. The effect of the intellectual disorganization attending the war and reconstruction was to accelerate these tendencies toward dispersal of sociological interests while at the same time giving a powerful impetus to sociological study as a whole, especially in Germany and in America.

The energies of the sociologists in America were mainly devoted to practical problems and the closely related problems of method. Disillusionment with the sweeping generalizations whose susceptibility to propagandist uses had been made all too manifest during the war emphasized the importance of objective, quantitative methods. While it was in the United States that the quantitative method was most ardently promoted, it was also applied extensively in Europe, notably by Leopold von Wiese, who would restrict sociology to the listing and characterization of all discoverable human interrelationships. American sociologists, particularly the Chicago school, developed an indigenous variant of the quantitative method, an elaborate technique of map making, in which various types of group and area configuration and change could be charted. The method is cumbersome and expensive but makes possible a fruitful cooperation of geographers, anthropologists and sociologists. Before the war the favorite method of practical sociological research was the social survey, which usually centered attention on such matters as housing, poverty or prostitution. The social survey was still employed after the war by the Geddes school in England but was being replaced in the United

States by more intensive studies of functional groups or areas and by the case method. The latter was given sociological standing by Thomas and Znaniecki's *The Polish Peasant in Europe and America* (1918-20) and it came to be widely used by sociologists seeking to emphasize the importance of the individual in the complex of social forces. Later certain anthropological sociologists who emphasized the uniqueness of every concrete situation attempted to apply the case method to the study of groups or institutions.

Such methodological changes, significant as they may be for the direction of sociological development, excited remarkably little interest in the nature of sociology as a science. A few scattering discussions of sociology as a humanistic or a natural science (Znaniecki); a faint repetition of the arguments for the study of the socialized individual (Floyd Allport) as against the study of collective behavior (R. Park); and scattering attempts at comprehensive classifications of social processes, made up the chief part of American post-war theoretical sociology. It was only the multiplication of textbooks that gave American sociology what appearance it had of definiteness of content.

In striking contrast was the richness of the discussion of purpose and method among German sociologists. It was animated partly by the desire to justify a new discipline and solidify its academic position, for sociology there had never attained important academic standing. A group of remarkable theoretical tendencies found expression in the post-war period. In 1921 a sociological journal was launched, the *Kölner Vierteljahrshefte für Sozialwissenschaften*, edited by Christian Eckert, Hugo Lindemann, Max Scheler and Leopold von Wiese. A number of research institutes were established, of which the best known is the one founded at the University of Cologne by von Wiese.

But the German interest in theory had a more positive quality as well; it was part of a general philosophical and methodological movement or group of movements which infused themselves into all German social scientific work. The central idea of this philosophy was the distinction between natural and cultural science, the first of which uses the method of description and analysis, the latter that of interpretation (*Erklärung*). The distinction was of course not new. In its modern form it was most clearly expressed in the work of Wilhelm Dilthey, E. Husserl and Max Scheler. Dilthey (1833-1911) stressed the

inadequacy of description and analysis in the social sciences. The method which he proposed involved the assumption that there is in a single experience a complexity of structure which forms the basis for an analysis of the essential elements of that experience and leads to the construction of ideal types of situation or character which serve as terms of reference for all future study. The influence of this conception was seen before the war in the psychopathology of Karl Jaspers; it was one factor in Max Weber's use of the type concept; and it found definite psychological exemplification in Edward Spranger's *Lebensformen* (1927) and *Psychologie des Jugendalters* (1926). The implications of the method were more profoundly developed by the logician and philosopher, E. Husserl, founder of what came to be known as the phenomenological school of thought. Husserl's work was essentially epistemology, but there was hardly a social scientist in Germany who did not feel the influence of his theories. The outstanding later representative of the school, Max Scheler, was philosopher, psychologist and sociologist. It was even more largely through Scheler's work that Max Weber was drawn within the influence of the school; the anthropology of Vierkandt, the history of Troeltsch, the Gestalt school of psychology all found inspiration in his methods. The more specific bearing of the method on sociology was summed up in Scheler's introduction to the *Versuche zu einer Soziologie des Wissens* (1924), a symposium of which he was editor. The book is composed of discussions of general and special forms and limitations of the cognitive structure. Scheler himself attempted to outline a sociology of knowledge. Sociology, according to the phenomenological school, should be the science of social relationships, but not merely of existential relationships. It is essentially the science of ideal types and categories of types. Scheler applied the method in an analysis of sympathy, or the phenomenology of love and hatred (*Wesen und Formen der Sympathie*, 1913, 3rd ed., revised, 1926).

Scheler's influence is an indication of the strength of the German reaction against positivism. Two other specifically sociological influences have to be taken into account in a survey of the German interest in theory: the work of Simmel in the delimitation of social categories and that of Tönnies in emphasizing the role of habit in social life and in distinguishing between society and community. Alfred Vierkandt and Leopold von Wiese made notable

attempts to link the ideas of these two scholars into one system. Vierkandt made use of the community-society distinction but was chiefly concerned with the universal motives that bring about social relationships. He regarded McDougall's theory of instincts as the most important contribution to the understanding of human nature in recent times. Von Wiese, the best known of the German sociologists of this period, sets out to classify the whole field of human relationships. The influence of the phenomenological school is seen in his insistence that neither *Beziehung* nor *Gebilde* can be defined directly but must be understood and defined indirectly. Von Wiese, however, differed from most of the followers of Simmel in his belief in the behavioristic and quantitative approach. He attempted to state his analytical hypothesis in quasi-mathematical terms; he used statistics and expressed an interest in behaviorism.

In Italy as in Germany sociology had no academic standing and its students came from other fields. Pareto in his economic studies developed an interest in a mathematical statement of social laws and his *Traité de sociologie générale* (1917-19) was an attempt to apply the method to sociology. Pareto insisted on the relativity of all laws. He set out with the assumption that the bulk of social actions are non-logical. Analysis reveals that the elements of social action are "residues" (habits of action), "derivations" (rationalizations) and utilities (maxima values, apparently a normative concept). There is no one explanation of social evolution; rather social equilibrium involves a mutual determining of all social forces. All social evolution, he concluded, is cyclical. His theory of the circulation of the *élite*, which explains social conflict as a struggle between the present aristocracy and the coming aristocracy, was credited with responsibility for the Fascist scheme of political and social ideas and action.

The dominant interest of American sociologists was psychological, and all their energies of classification went into attempts to work out acceptable groups of concepts which would explain the psychological basis of society and of the individual's actions in society. To this extent post-war sociology in the United States represented simply a refinement and elaboration of old aims.

The earliest concept, and the one which had the most enduring importance for sociology, was that of social forces. Small credited Ratzenhofer with originating it but Small made it over

and Ward popularized it. And the whole discussion of social forces was essentially an American preoccupation. In itself the concept of social forces is colorless but it was elaborated in a number of distinct and vivid forms. The most active controversy of the period centered in the doctrine of instincts. The fact that most sociologists, notably Giddings and Graham Wallas, used the doctrine of instinct so unquestioningly for a number of years after its introduction by McDougall in his *Social Psychology* (1908) indicates that it was regarded less as a startling theoretical innovation than as an effective formulation of accepted concepts. That McDougall should have reached this particular interpretation of the nature of social forces was a result of the increasing interest in biological explanations, and the reaction against the theory was in large part a phase of the environmentalist reaction against all extreme forms of biological determinism. It was in England that the first sign of opposition to the instinct doctrine appeared, in Morris Ginsberg's *The Psychology of Society* (1921). As the use of the hypothesis had been distinctly American it was natural that the attack upon the instinct doctrine should have been carried to a conclusion by American sociologists and social psychologists. Two adequate summaries of the controversy, C. C. Josey's *The Social Philosophy of Instincts* (1922) and L. L. Bernard's *Instinct, A Study in Social Psychology* (1926), both by opponents of the theory, brought to a conclusion the period of preoccupation with the instinct hypothesis and sociologists turned to other formulations of the nature of social forces.

Even before McDougall's enunciation of the instinct hypothesis, another group of concepts, that of social attitudes, wishes and habits, had already been used by a few sociologists and ultimately overshadowed the concept of instinct. Here the influence of William James with his emphasis on habits was of importance. As early as 1904, W. I. Thomas, at the St. Louis Congress of Arts and Sciences, stated that the important concepts of social psychology are those of attention, habit, sympathy, suggestion, attitudes, emotions; and in his *Source Book of Social Origins* (1909) he elaborated this idea. Cooley's discussion of the primary group and of the importance of communication for social development strengthened this general trend, while the influence of Freud's concept of the "wish" is easily discernible in the work of Thomas and Znaniecki in *The Polish Peasant*. The book be-

came so much of a classic that no American sociologist could afford to ignore its concepts, whether or not he used them. In an attempt to explain the process of social interaction represented by the Polish immigrants the authors developed the view that there are four fundamental wishes at the basis of all individual and social experience: the desire for new experience, for recognition, for mastery (later changed to response) and for security. In his own later works Thomas used the concept of attitude rather than wish. Park and Burgess also elaborated the attitude concept, and a large part of the activity of the whole Chicago school of sociologists was devoted to the discussion and classification of wishes and attitudes. A slightly different emphasis was given by Dewey to what is essentially the same concept. His various illustrations of the importance of mental activity rather than of mental structure played a part in leading many sociologists to a realization of the significance of attitudes rather than of hereditary impulses to action. In *Human Nature and Conduct* (1922) he attempted to elaborate a social psychology of habit and attitude. Analogous developments appeared in other countries, notably in the work of Hobhouse and the later work of Graham Wallas and von Wiese.

Another concept which had an increasing effect on the thought of all psychologists and sociologists was that of personality. James' work was here too of basic importance in the introduction of this concept, and Cooley was particularly influential in its dissemination. Among scholars of a wide variety of interests the idea of personality became the focus of study. In Germany there was the "critical personalism" of the philosopher-psychologist William Stern, who did a good deal of work in elaboration of his definition of the person as "unitas multiplex." The whole group of German phenomenologists was also interested in the concept, as was the psychoanalytic group of sociologists.

As the concept of personality developed it came dangerously near to the old group mind controversy, which in fact was not entirely closed. Floyd Allport contended that social psychology should discard the attempt to discuss groups or crowds and should use as a principle of explanation the concept of the individual in a social situation. He stood almost alone, however, not only in the United States but in most other countries, in his extreme opposition to the study of group behavior. Most other sociologists attempted to deal with the psychic aspects

of social groups, i.e. with leadership, tradition, fashion, imitation. This was perhaps a midway ground between the believers in a group mind theory and its extreme opponents. The work of Mary Follett exhibited a new realism in the handling of social forms, combined with a vivid appreciation of the importance of the group in determining an individual's thoughts. Her work was the best example of the theoretical foundation of the interest in functional groups.

In Germany there was still a certain interest in collective psychology. Theodor Geiger in *Die Masse und ihre Aktion* (1926) reviewed critically all the literature dealing with crowds and with collective action, especially Le Bon's theories, and Friedrich von Wieser in *Das Gesetz der Macht* (1926) analyzed leadership and collective action. It was in France, however, where the influence of Durkheim was still important, that the study of social psychology from the point of view of groups was most fully developed. While a number even of the followers of Durkheim questioned his emphasis on social factors, the majority of French sociologists were engaged in elaborating and further developing his idea of "collective representation." Publication of *L'Année sociologique* was renewed in February, 1925, under the direction of Marcel Mauss, a son-in-law as well as disciple and successor of Durkheim. The chief work of Mauss was in the field of primitive social organization. The clearest outcome of Durkheim's concept of "collective representation" was Maurice Halbwachs' *Les cadres sociaux de la mémoire* (1925) in which the main thesis was the contention that there exists a social framework of memory, a kind of collective memory, and that the individual consciousness is capable of recalling the past to the extent that it is placed in that framework and participates in that memory. René Hubert was influenced by a somewhat similar conception and Lucien Lévy-Bruhl developed in an extreme form the theory of the existence of a collective mentality.

A variety of specific interests emerged in sociological literature, such as the economic interest of Simiand and later of Bourgin and the anthropological interest of Lévy-Bruhl. In France the interest in religion was also important. Hubert and Mauss, for instance, made elaborate studies of the nature of sacrifice and Mauss developed a theory of magic. The work of Troeltsch in Germany on the social aspects of Christian dogmas exercised a widespread influence. Interesting sociological studies of art

appeared, particularly in France. The sociology of war was much less extensively developed after the war than it was before. On the other hand there were a number of studies of the sociology of revolution. Feminism received attention as a recent sociological force and the family continued to be an important subject of interest. After the appearance of Westermarck's *History of Human Marriage* (1891) emphasis shifted from a study of the instincts underlying the family to a consideration of the family as a social institution. At this point sociology very definitely came into contact with social work and psychiatry.

In the United States the work of Dewey, the spread of psychoanalytic doctrines, the mental testing movement as applied to adults and an interest in curricula for Americanization may be held jointly responsible for a series of books on educational sociology by Kirkpatrick, W. R. Smith, Robbins, Chancellor, Clow and Snedden. The American Sociological Society established a special section on educational sociology, while the faculty of New York University began in 1927 the publication of a *Journal of Educational Sociology*.

A more notable manifestation of the tendency of sociology to split into more or less distinct subdivisions was the appearance of the coordinate disciplines of rural sociology and urban sociology. Rural sociology was the first to develop separately. The movement derived force from agrarianism, particularly in European countries. In Germany von Wiese made important surveys of rural communities. The theoretical bases of rural sociology were the interest in regionalism and the interest in the community. Urban sociology was even more closely linked with regionalism. It was saturated with awareness of the predominantly urban character of western civilization. In the work of Patrick Geddes and Victor Branford urban sociology found definite form. Le Play himself was less interested in the city or the megalopolis than in geographic aspects of social organization. The study of non-territorial areas took its point of departure from Durkheim's study of totemic groups in Australia. The human ecologists combined an interest in territorial and in non-territorial areas.

This interest in regionalism was one of the main phases of the sociological interest in the community. Probably unconsciously the American sociologist took over Tönnies' distinction between community and society and concen-

trated attention on the basis of community life. A number of sociologists were chiefly interested in the economic phase of community life and organization; the rural sociologists were concerned with all kinds of helpful community organizations. This interest was definitely linked to the community organization movement of the social workers and to the whole city planning movement.

Among the special fields assiduously cultivated by sociology, immigration and other problems of population were the most important. The American restrictive immigration laws aroused an interest in the problem not only among American sociologists but among the French, Italian and German as well. For social science the discussions of immigration were important chiefly for the impetus they gave to a revival of interest in the process of assimilation and in the quantitative aspects of population.

The interest in assimilation was predominantly American and closely connected with the Americanization movement. The race hatreds precipitated by the war brought the subject more into the foreground of thought, although scientists were for the most part interested in the racial controversies through the approach to be had from the biology of heredity. This interest in heredity was closely linked with the eugenics movement, but from the point of view of the social sciences eugenics declined in importance after the war. Its literature was extensive but it was in the main a literature of popularization. The birth control movement, however, made important advances in both scientific and popular interest after the war. In 1916 the British National Council of Public Morals set up the National Birth Rate Commission, which has since then made an important series of investigations and reports. Considerable impetus was given to the movement by Marie Stopes in *Contraception, Its Theory, History and Practice* (1923).

This increasing popular interest in eugenics and birth control was added to the question of immigration as a further factor in the recrudescence of interest in the quantitative aspect of the population problem. For a number of years before the war whatever interest there was in population centered around problems of quality, in other words the eugenic interest. It is true that in both France and Germany there was a considerable amount of militaristic and nationalistic large family propaganda; and in the

United States Roosevelt made capital of Ross's phrase "race suicide." The populationist views of statesmen and moralists, however, excited little interest in scientific circles, nor was there much scientific interest in the problem of excessive population. But the widespread destruction of natural resources in the war led to new attempts to survey the quantity of resources available for an increasing population. The effect of the discussion was a revival of Malthusian fears of a future clouded by overpopulation and poverty with a consequent restlessness menacing to world peace.

A wealth of books dealing with the problem appeared during the decade, designed primarily for a popular audience. Sir George H. Knibbs, statistician for the Commonwealth of Australia, in his *Mathematical Theory of Population* (1917) made some striking calculations on the result of continuation of present rates of population increase. Keynes' *Economic Consequences of the Peace* (1920) stressed population pressure as one of the three or four greatest factors in world instability. The most striking single contribution to the literature was the formula for population growth of Pearl and Reed. In *The Balance of Births and Deaths* (vol. i, 1928) Robert Kuczynski made an important statistical study of the falling birth rate and his work indicated that western Europe is on the way to depopulation. The concept of the optimum, which emphasized social factors and the relativity of standards of living and possible population increase, was one of the most fruitful techniques introduced into discussions of the population problem. Carr-Saunders made use of the idea and A. B. Wolfe was one of its most enthusiastic proponents in America.

Criminology was one of the early collateral interests of the sociologist, but so long as it was dominated by the biological conceptions of Lombroso and his school the sociologists' interest was a derivative one, entering by way of penology. In 1913, however, Charles Goring wrote *The English Convict*, a work based on extensive statistical studies. This book operated to dispel faith in the thesis of a hereditary criminal type and prepared the way for a new interest in the mentality of the criminal. After the war criminology took on new life and new forms and was drawn closer to the other social studies. The rapprochement was achieved largely through psychiatry and abnormal psychology. The wide dissemination of psycho-analytic methods after the war exerted a pro-

found influence upon the tendency to explain the criminal in terms of psychiatry.

As a result of this changed emphasis criminology became more and more concerned with the understanding of the individual offender. Case study methods were borrowed from social work and psychiatry and an immense volume of psychiatric-criminological material accumulated. The pioneer work was that of William Healy in his *The Individual Delinquent* (1915). The study of the individual delinquent was closely linked to social work and to child welfare activities. It led to numerous studies of the juvenile courts, of which the best known was the work by Jane Addams and others, *The Child, the Clinic and the Court* (1925). The movement drew much material also from studies of family disorganization, as evidenced in Joanna Colcord's *Broken Homes* (1919) and Ernest R. Mowrer's *Family Disorganization* (1927).

While the prevailing tendencies in criminology were social and psychological, the biological tendency received new impetus from the study of mental tests and from endocrinology. The hereditary defective or the victim of glandular unbalance are types hardly less definite than the atavistic types of Lombroso. An excellent American example of this tendency was *The New Criminology* (1928) by Max G. Schlapp and E. H. Smith. The tendency was much stronger in Europe, however, than in the United States. In Spain *La criminalidad y las secreciones internas* (1927) by Mariano Ruiz-Funes was a formidable work which set forth all the biological explanations of criminal behavior, with chief emphasis on endocrine theories. Criminology after the war in Germany was largely criminobiology. The Austrian, Adolf Lenz, in his *Grundriss der Kriminalbiologie* (1927), attempted to create a whole biology of personality in terms which are reminiscent of Lombroso.

One of the most notable developments in the war and post-war periods was the progress toward professional standing of the group of workers attached to the administration of practical social services. "Applied sociology" had covered in a fashion the broad field formerly known as charities and corrections. It had operated on the principles of scientific inquiry uncovering, so far as it could, general rules which might arrive at practical application through legislation or through the administration of public or private charitable services. The charity organization societies of the nine-

teenth and early twentieth centuries represented a half-conscious reaction against the impersonal functioning of applied sociology and an impulse toward direct and continuous participation in the government and administration of social service. At the close of the pre-war period the professionalization of this form of activity was well under way and a systematic technique was developing. The traditional term "charities" gave way to "social work" which, however, covered a much wider field. The methods of social work penetrated into the fields of criminology, public health, education, labor administration, the administration of social insurance.

Social work addresses itself to the concrete case. It is no part of its province to map out the road for social legislation, to determine the direction of social progress. These general issues are committed to political science, sociology, economics. Social work seeks to translate the general social intent into rational application to the concrete case. Accordingly the central point in the social workers' system is occupied by the technique of social case work. It is a technique which must naturally exhibit great flexibility, since it serves such widely divergent interests as those of the broken family, the convalescent, the psychiatric patient. Such a technique had gradually evolved in the decade preceding the war. The publication in 1917 of Mary Richmond's *Social Diagnosis* supplied the social worker with a practical manual which remained the dominating work in the field, although a number of other excellent works appeared.

The immediate effect of the war on social work was vastly to increase the demand for trained social workers in connection with hospitals and convalescent camps, the relief of soldier's dependents and the administration of vast social programs such as Belgian relief during the war, and after the war Near East, Central European and Russian relief. There were, however, more subtle and profound forces affecting the position of the social worker in his relation both to social science and to public administration. The war had broken down the conception of an essentially laissez-faire state, standing aloof from the normal independent citizen and intervening only in the special instance by way of charities or correction. The stresses of the war years had broken down much of the social economic structure on which the fortunes of the normal independent citizen were based. It had become a primary obligation of the state to hold the tottering citizen on his feet—

not a charitable obligation, but one of sane public policy. The services of the social worker were required to determine where and in what form support should be extended. He ceased to be an exponent of the griefs of the needy, pleading for relief in semi-religious accents, and became instead the expert investigator or administrator attached to a rational public service. In European countries, where the destruction of traditional forms of thought had been most severe, this change in the relation of government to the handicapped was tacitly accepted, and social work, with all the technique of social case methods, was maintained by the state. In America the charitable tradition persisted and social work was maintained chiefly by private funds. Nevertheless, the collection of these funds was undertaken in many cities through community chests and was levied with almost the finality of taxation upon those who were able to pay.

While the advancement of social science is no avowed objective of social work, the immense volume of concrete data investigated by the social workers provided a sound basis for studies of purely scientific intent. The methods of social work were freely drawn upon not only by sociology and its dependent disciplines, but also by students of industrial and agrarian problems. The place of the social worker in the circle was one of steadily increasing importance.

VI. ECONOMICS. The key to the interpretation of economic thought during the war and the post-war decade is to be sought not in the prevailing intellectual mood but in the revolutionary changes in the economic situation and the inevitable if lagging readjustment of economic ideas. For earlier periods the interpretation of movements of economic thought in terms of economic institutions often appears somewhat strained. The world of scholarship is always in some measure autonomous, and when external conditions are virtually static, scholarship may yet exhibit remarkable advances, governed by forces evolving from within. For the period here under consideration the relation between institutional change and changes in the direction of thought is compelling, direct and obvious.

More than any other war in history the World War was predominantly economic in character. The application to military use of all the resources of modern science increased tremendously the voracity of the battle line. From month to month the requirements of arma-

ments, munitions and supplies increased at an accelerating rate, until severe strains began to appear at innumerable points in the industrial system. Before the war was over every country engaged had come to a full realization of the dependence of its armies upon the functioning of its industry. The "industrial front" was no longer a mere metaphor. Battles were being won or lost in the factories hundreds or thousands of miles away from the sound of the guns.

In consequence government and private industry were forced to work out a new relation, not easily definable in terms of the traditional political and economic theory. The government no longer stood apart from industry, practising paternalism or laissez-faire according to its established habits. Government and industry joined in close cooperation to advance the common national interest. There were indeed disputes as to prices, profits, taxes; these were resolved, however, not in terms of the rights of the individual as against the state, but in terms of the efficient functioning of the whole organism.

American experience in the cooperation of industry and government is perhaps more illuminating than any other, since America entered the war with a full realization of the new developments. As soon as war was seen to be inevitable the representatives of every important industry flocked to Washington to volunteer their services as "dollar-a-year-men." For its machinery of industrial control the government had the choice of the ablest key men in industry, men possessed of an amount of vital information on the functioning of industry such as government had never before had at its command.

Government and industrialists working in the closest harmony set about organizing and applying to war uses every available resource—labor, materials, credits, power. Questions of the distribution of rewards were in abeyance: if wages were advanced it was solely with a view to increasing productive efficiency; prices were fixed at levels calculated to bring out the fullest supplies; credits were distributed on the basis of national uses rather than relative profitableness.

The first impulse upon the close of the war was fully to "demobilize" industry; to return to the private scramble for profits with the government keeping the ring. Gradually it came to be realized that the pre-war economic order could not be reestablished integrally. The problems of war debts, indemnities, markets, supplies of raw materials, employment, the distribution of credit, transcended the competence of the old

formulae. Government and business had to cooperate formally or informally in working out their solution.

Even in the United States, where the disintegrating effects of the war were least in evidence, the tendency of government to cooperate with industry appeared in the official interest in standardization and the elimination of waste; in the sympathetic attitude toward consolidations that would have been highly suspect in the era of "trust busting"; in the repeated attempts to apply the resources of the Federal Reserve system to promote sound business development and to discourage waste and immoderate speculation. Even in Russia, where the old economic order had apparently been entirely destroyed, it was necessary for the communistic government to devise a "new economic policy," with a view to securing the cooperation of private interests at home and concessionary interests from abroad. Between these two extremes Germany, Czechoslovakia, Italy, and in a less degree England and France exhibited unmistakable tendencies toward a new integration of government and private business.

In the new institutional situation a host of practical problems emerged, requiring the services of the economist as expert. During the war economists and statisticians in every country were drawn into the services of the government to assist in the elaboration of fiscal policies, the administration of credit, transportation and power, the control of raw materials and the production process, the adjustment of industrial relations. Even before the war the employment of the economist as expert in industry had become common in Germany and not infrequent in America. The experience of the war enhanced the general estimation of expert economic services and greatly widened the scope of their practical application. In consequence the outlook of economists became semi-professional, with an emphasis upon practical solutions of concrete problems rather than the large generalizations of pure scholarship.

Hardly less significant in determining the development of economic thought was the special character of the problems of economic policy which loomed largest in popular interest. Inflation, the burden of taxation resulting from the colossal increase in public debts, indemnities, debts owed by one nation to another—all familiar problems in every respect but magnitude and therefore with an extensive traditional literature to draw upon—were discussed with

great acumen but as a rule without new insights of far reaching importance. Hardly any part of the voluminous literature on the economic consequences of the peace, Germany's capacity to pay, the possibility of the payment of inter-Allied debts, the incidence of taxation, the effects of inflation, took into serious consideration the change in the relation of government to industry or the emergent internationalism of the economic system. Although this literature was characterized by abundant information and sound sense, as an intellectual phenomenon it was reactionary, harking back to the epoch of John Stuart Mill and Cairnes.

The diversion of economic attention in the direction, on the one hand, of problems of practical economic administration and, on the other hand, of problems of public policy capable of a traditional solution left the science without the concentrated energy requisite for significant systematic formulations. No great treatise of economics appeared in this period. Criticism of the older theories was carried on persistently, but with no intense conviction as to the importance of the issues. Whereas the earlier criticism had derived most of its animus from serious concern over the justice or injustice of the economic system (Clark, Böhm-Bawerk, Hobson, Sombart, Veblen), the newer criticism was animated chiefly by concern over pure scientific canons and the felt need of bringing theoretical conclusions into line with the results of empirical inquiry. Thus the demand and supply curves constructed on rational principles by Marshall were confronted with altogether dissimilar curves that had been derived from actual market data by empirical methods; the concept of the "representative firm" was subjected to empirical tests and found wanting; the classifications of industries by the rate of return were proclaimed "empty economic boxes." Attempts were made to reforge the weapons provided by the older theory: moving equilibrium was proposed as an elaboration of and substitute for the concept of stable equilibrium, and the law of balanced returns was proposed as a substitute for that of increasing and diminishing returns. A great deal of work was done in various fields in an attempt to complicate and refine those theoretical categories which promised to be useful in dealing with descriptive and quantitative material. The results were hardly satisfactory. Eventually demands were made for a complete reformulation of theory so as to transform it into a true

organon for dealing with statistical generalizations.

The new trends in theory pointed in the direction of the institutional factors in economic life and to those types of schematization which assigned more importance to the effectiveness of these factors. In textbooks the historical relativity of the present order and the interplay of economic with other factors were emphasized at the expense of the refinements of marginalism; descriptive material was more abundant and occupied a more independent place than its merely illustrative uses would permit. Although attempts were made in some texts to dispense completely with the older theory—of these the most notable is the *Grundriss der Sozialökonomik*, the modern substitute for Schönberg's *Handbuch*—they by no means provided a substitute for old fashioned *Principles*; the best of them remained on the level of a sketchy delineation of the present system and of a compact historical and statistical description of its several parts.

In Germany there was a revival of theoretical interests best represented by the realistically tempered marginalism of Schumpeter. The vogue enjoyed by Cassel was at least partly due to his dispensing with the metaphysics of utility and value. Spann's universalism—a revival of the organismic romanticism of the early nineteenth century—abolished the individual and the concept of causality altogether. In France solidarism acquired a more respectable academic standing and a wider following. There was more emphasis in England, even among the older theorists, on the irrational character of human behavior and more interest in the way economic phenomena change as against the search for the causes of their existence. In the United States, in addition to a proposed displacement of the older theory by a system of empirically ascertained relations between economic variables, there was a great deal of discussion, most of it on the methodological level, of the application of modern psychology to economics, of the value of the institutional concept and of the functional as against the structural approach.

A distinct line of theoretical work, in the United States, grew out of the preoccupation with problems of public regulation of monopolies. The issues of monopoly charges and valuation had of course been vigorously discussed throughout the generation preceding the war, and a voluminous literature had been accumu-

lated. The newer analysis emphasized the fact that natural or legal monopolies possess features which increasingly characterize the rest of the economic system. Overhead costs attracted attention because they make regulation on the basis of the older theory impossible. The discovery of the ubiquitousness of this phenomenon led to conclusions which undermined the price theory based on assumptions of automatic adjustment of production to demand and of price to cost. It made essential a new theory not only for the uses of rate regulation but also for the intelligent comprehension of the realities of price determination in a market with an inelastic demand and a still less elastic supply. In this connection John R. Commons proposed a new approach not only to the question of monopoly but to the general economic problem. Economic life was to be viewed as a series of transactions entered into by going concerns guided in their activity by working rules, rather than as the movement of commodities according to a principle of scarcity effectuated by mechanistically conceived entrepreneurship.

The post-war period was unusually rich in experience in the field of currency, and the impetus to theoretical analysis was strong. Irving Fisher's symbolical formulation devised before the war seemed to make the quantity theory available for dealing with concrete situations involving a rapid increase in circulating medium and a rapid rise in prices. The equation of exchange was refashioned in a number of ways largely for the purpose of bringing to the fore the factors of importance in determining changes in the general price level. Of these bank credit occupied the center of interest. This led to a deliberate departure from the commodity theory of money and deprived the quantity theory of its causative, explanatory character. With the general recognition of the ability of organized banking to extend or contract the volume of circulating credit, the advocates of control and stabilization turned their attention to banking policy rather than to monetary policy; proponents of social reform began to inquire whether a rationalized distribution of credit, not only among producers but between producers and consumers, might not serve toward the rational development of industry and the elimination of overproduction and underconsumption and toward the regularization of employment.

Allied to the quantity theory was the purchasing power parity theory in foreign exchange

This century old doctrine underwent in this period a series of modifications which endowed it with greater logical validity but deprived it of practical effectiveness. The regime of inconvertible paper money, for which this theory attempts to set up a parity, led also to certain adaptations in the theory of international trade. The analysis proceeded, however, almost entirely on the basis of the classical assumptions; it disregarded the important novel factor in the situation, the increased international movement of capital, with consequent deflection of rates of foreign exchange from commodity parity and ultimate revision of reciprocal demands and the comparative cost of commodities.

The developments in the field of economic history were notable. One effect of the violent changes in the whole economic system was to emphasize the need of systematic studies of change, not only in crisis periods but even more in the more manageable periods of gradual development. Painstaking factual studies tended to displace large generalizations, and scholars in increasing numbers turned their attention to the possibility of applying rigorous statistical methods to historical inquiry. Most attention was paid to clearing up the origin of capitalism and to the industrial revolution. Sombart's revision of *Der moderne Kapitalismus* (1921-27) assigned greater importance to commerce in making possible the original accumulation of capital and reflected the influence of the times in putting more emphasis on the role of the state in the creation of the modern order. Tawney's *Religion and the Rise of Capitalism* found the spiritual preparation for the acquisitive order in the teachings of early Puritanism and in the later breakdown of those restraints which made economic virtues work out to the benefit of the community. Monographic research found the dominant forces of early modern capitalism in the commercial expansion of the seventeenth century and led to the conclusion that technological advance assumed its importance in industry only in the second quarter of the nineteenth century. The priority of England in the development of industrialism was challenged and the dark picture of "evils" of the industrial revolution was found to have been considerably overdrawn. The drift of the later monographic literature on American economic history was likewise in the direction of breaking up the rigidities of earlier formulae. It was enriched by compilations on the history of manufactures, agriculture and transportation,

by a number of sectional studies and histories of separate industries and railways, and finally by several histories of the labor movement stressing the importance of different factors in conditioning the development of this movement. While the achievements of theory and history during this period are interesting in detail, the more impressive achievements of the economic science of the time were closely connected with practical interests. Here the quantitative method was indispensable; it was applied so widely and with so great an application of intellectual energy as to create in many minds the impression that the future of economics lay wholly in the field of quantitative analysis.

The statistics available to the inquiring economist increased in this period enormously. Enumerations of the census type increased in frequency, in scope and intensity and in the reliability of results obtained. Governmental regulation and industrial reorganization on a national scale required a fairly accurate statistical description of major branches of economic activity, followed up by registration of current changes in the more important factors in the situation. The government and its numerous agencies, associations representing organized industries, the banks and investors' organizations, kept a close watch on economic developments, trying to measure, each for its own purposes, the tempo of economic activity in its multifarious manifestations. There was an extraordinary development of methods for dealing with quantitative material, for bringing it into a manageable shape which would admit of comparisons with the past and with related lines of economic activity. Index numbers, which were in wide use even before the war, were subjected to a theoretical analysis which systematized the various methods of compiling them and brought out their significance for the purposes in hand. Time series analysis was adopted from the natural sciences and employed to distinguish different types of changes in economic series. Although attempts to provide a probability basis for the use of refined mathematical techniques in economic statistics were unsuccessful, the validity of these methods for purposes of statistical description was generally granted.

The accumulation of statistical materials and tools was also stimulated by the study of industrial fluctuations. Even before the war it was fairly clear that the study of the business cycle was not an investigation of the "short run," disregarded by orthodox theory, nor an eco-

conomic dynamics building upon and supplementing the theory of statics, but an entirely different envisagement of the economic order, a scheme in which the normal was not a stable equilibrium achieved in the long run but a certain regularity and uniformity of change. The theories of this period, most of which stressed causes lying in the credit and currency mechanism or in under-consumption, were formulated in such a comprehensive way as to bring about a wider recognition of the fact that the real explanation lay in the disparity in the movement of various economic factors and in the accumulation of the effects of this disparity until a breaking point is reached. Mitchell's presentation of the subject, published in 1913, was increasingly recognized as a framework which permitted a quantitative study of separate elements in the situation, intended at once to ascertain the realities of their functioning and to bring out in increasing detail the part played by these elements in the congeries of strains and stresses which was called the business cycle. Attempts were made to trace out the secular movements and on this basis to construct the "natural history" of industry, in which the forces at work are the growth of population, frequency of inventions, building up of the capital structure. Extension of the investigations to include a longer period of time and the application of a more refined technique resulted in uncovering "major cycles," the rationale of which was traced by various authors to important changes in economic organization or to changing trends in gold production and gold values.

The luxuriant growth of quantitative economics constitutes perhaps the outstanding characteristic of this period. It was first developed in the United States and later widely imitated in other countries. Stimulated by the fundamental changes and by the wide amplitude and universality of cyclical swings in the years immediately following the war, a number of organizations were established which devoted themselves to the digesting of results of current observation and to the intensification in many directions of the study of correlations between economic variables. They were supported by government and business organizations because they offered the possibility of finding ways and means of mitigating the violence of fluctuations and of anticipating developments in the proximate future. The institutionalization of research was not confined to quantitative studies; it developed almost equally in the field of descrip-

tive studies. Such extensive fact gathering and condensation could not be conducted by a single individual, even with the unskilled assistance of seminar students.

The effect of the war and post-war developments on the labor problem was confusing in the extreme. At the outset the traditional assumption of diametrically opposing interests between labor and capital prevailed. In all the warring nations the first demand of government was merely a truce in the industrial struggle. Gradually it came to be recognized that something more than a truce was needed. The labor organization, like the corporation, could be employed as an instrument of national defense. Before America entered the war the labor organizations were already tacitly recognized in England and Germany as important factors in maintaining morale and stimulating production. America profited by European experience and from the outset recognized the official labor organizations on a parity with other directive forces in the economic system. For purposes of efficiency and control the extension of labor organization over parts of the field that had been hitherto non-union was permitted.

To stimulate the efforts of the worker, wages were advanced, sometimes merely as an offset, partial or complete, to the advancing cost of living, sometimes in more generous measure. What is essential is that the worker's standard of living came generally to be regarded as a matter of national concern. This attitude toward wages and employment was carried over into the post-war period in the European countries and the position of labor remained a dominant political concern. In America the first impulse of the smaller business concerns was to "deflate" wages but the great corporations, having become adjusted to the conception of operation in conformity with national interests, hesitated to take part in this deflation. Within a short period industry entered upon a phase of prosperity and the theory gained currency that this prosperity was due to the large spending power of a well paid working class.

In the development of tactics notable innovations were made by both capital and labor. Immediately after the war the employment of "industrial relations" experts was extremely common, and this implied a deliberate attempt on the part of the management to operate on a basis of understanding. Employees were encouraged to form shop committees and company unions for the regularization of industrial rela-

tions—often indeed as a prophylactic against unionization. Labor made numerous attempts to strengthen its position through the assumption of new functions such as banking and co-operative merchandising. In some instances remarkable results were achieved.

In labor theory the period yielded little that was new beyond the remarkable doctrines of the manifesto of the British Labour Party immediately after the war, which envisaged a state accepting as the definitive object of its policy the satisfactory supplying of the requirements of the democratic masses, and the fugitive literature in America occasioned by the launching of the abortive "Plumb Plan" for railway labor. There was, however, a rich monographic literature on various phases of labor legislation history and tactics.

Economic literature in general exhibited a lack of drive and direction. For this the explanation appears obvious. The world of economic fact was profoundly changed by the war. The old general concepts implicitly assumed in economic thinking—the state, private enterprise, the nation, internationalism, credit, capital—had taken on new meanings and time was wanting to weave the changed concepts into a harmonious structure of thought.

VII. POLITICAL SCIENCE. Traditional political science had already begun to exhibit signs of disintegration before the outbreak of the war. The neat concepts of the early twentieth century were subjected to severe criticism from the point of view of political realism. The "politics of power," which manifested itself with increasing frequency in the last decade before the war, had operated to weaken the position of the state as a moral entity. As an incarnation of force the state might be expected to vary in form and function with the resources at its command.

The immediate effect of the war was to dispel political questionings of every sort. In the nations at war the competence of the state became virtually coextensive with the national life. The economic system yielded up its independence in the name of military necessity; partisan differences were smoothed out in the interest of national unity; individual liberty was unceremoniously brushed aside. Professional political scientists, to be sure, maintained a formal consistency with peace time doctrines, but the concepts and formulae of the intellectual world at large were simplified to the last degree of absolutism.

With the progress of the war a host of new problems arose to disturb the absolutistic formulation. Within the nations at war the issues raised by conscientious objectors and by sporadic opposition to drastic labor control reopened the question of the unlimited character of sovereignty. In the neutral world criticism of a more general character awakened. On the widely accepted assumption that the war had been forced by militaristic influences operating within nations otherwise peaceful, a significant discussion arose as to the proper relation between the military and the civil authorities of the state. A striking comparison was drawn by Munroe Smith between German policy as dominated by Bismarck and as dominated, presumptively, by the military group surrounding Wilhelm III. The "imponderables" in policy, upon which Bismarck had laid so much stress, were now erected into an important limitation upon sovereign action. Most important of all, belligerent propaganda and neutral criticism were shaping up conceptions of war guilt which tacitly implied moral limitations upon the sovereign state and its responsibility to the "family of nations" or to mankind. The concept of a "superstate" was forcing itself upon popular political science, in spite of the rigidity of nationalistic preconceptions. In its extreme form this formula of the subordination of state to superstate went so far as to dispute the legitimacy of a government which was assumed to have flouted its responsibility to the family of nations. Woodrow Wilson's distinction between the German government, deserving to be crushed in war, and the German people, against whom the charge of guilt would not lie, was an instance directly in point. The tacit assumption of a superior international political entity appeared repeatedly in Wilson's pronouncements. Even the apparent harking back to a moralized nationalism in the formula "the self-determination of peoples" involved an internationalistic assumption. The right of self-determination rests not on natural rights, but on an assumed moral world order.

Discussion of an international political order became almost a universal preoccupation after the Peace Conference and the launching of the League of Nations. The discussion involved the position of the sovereign state within the new order; the relative weight of large and small nations in a working international organization; the canons of treaty making; questions pertaining to judicial action in international disputes;

the use of military force and economic pressure. Political scientists, philosophers, historians and other scholars participated in the discussion, but the main burden of it was borne by statesmen and political leaders. A wealth of literature appeared, but it would be hazardous to say that any single work stands out as an adequate treatment of this international trend of thought, although it was by far the most important in the political science of the period.

Parallel with the elaboration of the international order into an increasingly realistic entity, the attack upon the doctrine of the omnicompetent state was carried through with great critical energy. The most effective criticism was launched by the pluralists, led by Harold Laski. To the pluralists the state is simply one out of a number of associations to which the individual belongs and as such has no exceptional moral claim to be obeyed. The superiority of the state to other associations rests on its power to use coercion. The controversy over pluralism produced a flood of literature and resulted in a reiteration of the distinctions established before the war between various meanings of the term sovereignty. It led to an ethical defense of the superiority of the state by Elliott, who interpreted sovereignty as the assurance of the community of purpose that is the essence of the state. The same problem was approached historically by MacIver in *The Modern State* (1926). His conclusion was that the proper sphere of activity of the contemporary state is the dictation of such actions necessary for the good life of society as can be enforced, if necessary, by physical forces.

In Germany and Austria the question of state sovereignty was discussed chiefly in connection with the relation between state and law. The most novel development was that of the Kelsen school. As a neo-Kantian, Kelsen distinguished between *sein* and *sollen*, realms of existence and essence. Positive law is a closed system of postulates in the realm of essence and therefore does not recognize phenomena on the existential level. It deals not with acts of physical beings but with legal relations. The state, which is the source of law, is a juridical person, the subject of rights and duties. The *reine Rechtslehre* of Kelsen made it possible to conceive of sovereignty also as a legal relation, as the binding validity of the legal order, its internal coherence. To Fritz Sander, who differed slightly from Kelsen, the state was essentially no more than a particular system of legislative, administrative

and other procedures. Somewhat more realistic was Leonard Nelson, who believed that while force cannot make law it is necessary in order to make law effective in society. This is the purpose of the state. The power of the state, which is the supreme power, must, however, be a legal one, that is, must itself be limited by law. Still more realistic was Wolzendorff, to whom the state was a ruling force but a force of order, not of arbitrary compulsion. The state's function is to become the responsible and final guarantor of the law, to intervene only where free individual or associated action becomes insufficient. Finally Carl Schmitt, holding that political philosophy is nothing more than secularized theology, identified sovereignty with arbitrary power and found that it is exercised in the numerous situations which have not been foreseen by legal prescription.

Another development which marks this period was the concerted attack on the democratic form of government. The establishment by psychology of the extreme variation of mental ability led to the questioning of democracy on general grounds. A certain disillusionment with democracy was apparent even in the late works of James Bryce. Democracy was made the subject of a more realistic study in the countries which hitherto had not been under a democratic regime and was vigorously championed in spite of the paraphernalia of democracy in action, such as political machines, manipulated public opinion and lobbying. The influence of economic interests on political activity led to a demand for a substitution, or at least supplementation, of territorial representation by functional representation so that economic interests might have a direct share in the determining of governmental policies. Functional representation, it was asserted by the advocates of the council form of government in Russia and Germany, would provide the nearest approximation to direct democracy possible under modern conditions. In the Anglo-American world the problem of functional representation was a part of the larger controversy centering in pluralism and as such attracted considerable attention both on its own account and in connection with the coordination of organs of functional representation with organs of territorial representation.

Similarly parliamentarism was being seriously discredited. Carl Schmitt, following Smend, defended true parliamentarism on the ground that it offers publicity of discussion of all impor-

tant state measures in advance of decision. He asserted that latter day parliamentarism was degraded because vital decisions were taken not in plenary meetings of representative assemblies, but in small committees sitting secretly. Genuine parliamentarism, involving a nice balance between the legislature and executive, was distinguished by Redslob from monistic parliamentarism of the French type, where the sovereignty actually resides in the Chamber of Deputies and its committees.

The defense of dictatorship represented the obverse of the attack on democracy. Before the war G. Mosca had asserted that the mass of the people is incapable of self-government, that it is always managed by a minority and that a change in the form of government means merely the transfer of power from the hands of one minority to that of another. The defense of dictatorship received a peculiar twist in its application to the Russian situation. Lenin and Trotsky, adopting the syndicalist contention that the parliamentary state, with a venal press and corrupt parties, represents the dictatorship of the bourgeoisie, insisted, in opposition to Kautsky, that dictatorship of the proletariat, a recognized transition stage to the abolition of the state, cannot be achieved by the peaceful means of obtaining a parliamentary majority. Communist theorists assigned to the state a function far superior to any it ever had in socialist discussions. Communism, although still conceived in terms of economic and social organization, was to be brought about through an effective utilization of all the powers at the disposal of the state during the prolonged period of its domination by the vanguard of the class conscious proletariat.

These years after the war exhibited an increased attention to factors which condition international relations and the channels through which these factors become effective. The study of policies which result in the clash of national interests and of the methods by which these clashes can be avoided became a recognized division of political science. Most attention was given to the economic factors: the desire for the control of important sources of raw materials, of markets for goods and capital, of lines of communication, of overpopulation. Recognition of the predominantly economic character of imperialism led to a discussion of its essential relation to the existing economic order. Imperialism was considered by some the inevitable accompaniment of monopolistic, parasitic cap-

italism; by others the survival of feudalistic militarism grafted upon the modern economic order. Much attention was given to possible methods for abating the causes of disputes between nations and for the replacement of unregulated international competition by cooperation—international regulation of foreign investments, migration and the control of raw materials.

Of the institutions important in foreign policies most attention was paid to diplomacy and the press. It had long been recognized that the control of foreign relations was the weakest point in a democracy. The war produced a revulsion against secret treaties and a demand for "open agreements openly arrived at." The studies in this period, however, made it clear that while the first part of the formula is practicable and would lead to the cessation of leagues and alliances directed against third parties, public negotiation is not always practicable. It was also contended that in a democracy there is about as much control over foreign policy as over any other affairs of state and that the development of genuine control depends upon the creation of an informed and instructed public opinion.

Advances in the study of public administration were conditioned by the increasing dominance of the expert in the administrative machinery. Even before the war the relation between the permanent civil service and the cabinet responsible to parliament had been much debated, and in the post-war period the instability of cabinets and the growing group consciousness of civil servants made the problem more acute. The question of judicial review was also raised in a more compelling way after the war by the increase in administrative rule making; the underlying issue was whether the courts or the administrative commissions are the more flexible and more rational regulatory agencies. Parallel with the interest in the distribution of control was the concern with efficiency of functioning. Methods developed by industrial psychology for testing the fitness of the job holder were adapted to the usage of the civil service and measures were devised for testing the efficiency of performance of various governmental units. New schemes of administrative organization were worked out with an eye to eliminating waste due to duplication and overlapping and the general clumsiness of structure. The work of the Institute of Government Research in the United States and of the Institute of

Public Administration in England were of particular interest in this field.

In the United States much attention was given to the continuing tendency toward centralization of authority in the federal government; to the installation of the budget system by the federal and many state governments; to the increase in number and the extension of competence of administrative commissions; to experiments in the field of municipal government and later in rural local government. In the British Empire interest was centered on the devolution of powers resulting from the tendency toward independence of the self-governing dominions. Much was written in Germany in connection with the new constitution. Attention centered especially on the relation between the Reich and the constituent states (*Länder*), on the position of the new advisory economic councils in the general administrative system and finally on the question of judicial review of legislative enactments. In Italy the focus of interest was the reconstruction of the entire state apparatus from the top down. The chief problem occupying Russian political scientists was the regularization of governmental processes as a means of escaping the crude and arbitrary dominance of revolutionary intuition.

Political science was markedly influenced in this period by developments in related disciplines. The substitution of sociological for legalistic conceptions of the state made it imperative to redefine what is specifically political. An easy solution was found by some in reviving the notion that the characteristic attribute of the state is its power of physical coercion. Fundamentally related to this was the view held by others that the state is the resultant of attitudes engendered by the possibility of organized conflict. Political science so defined could still retain its identity even if its scope were extended to include the study not only of governmental agencies but also of the numerous underlying groups of organized interests.

Social psychology contributed to politics perhaps even more than sociology. In the preceding period Graham Wallas had stressed the importance of a human nature approach to political processes and Michels had pointed out the danger of democracy degenerating into an oligarchy because of the unscrupulousness of its party leadership. While work along these lines continued, new leads were uncovered. Mary Follett pointed to the vitalizing and integrating role played by conflict in the social process,

analyzed the nature of group organization in terms of a somewhat modified behavioristic psychology and indicated the significance of the group in a democratic state. Walter Lippmann gave an interpretation of political behavior which emphasized the importance of stereotypes in the formation of public opinion. An impetus was thus given to numerous studies of the structure and functioning of political parties, of the formation and manipulation of public opinion, of revolutions and revolutionary movements.

The application of psychology to political science was carried farthest by Floyd Allport. In renouncing the "institutional fallacy," by which institutional attitudes of individuals are abstracted and set up as entities in themselves, he claimed the whole field of the social sciences for the study of behavior attitudes. This behavioristic approach naturally led to attempts to reduce politics to statistical expression, such, for instance, as the correlation of voting with a number of factors which are supposed to influence it. Measurement and precise description were used also in the political survey, which developed first in urban communities in the United States and was later employed in the field of operation of state and federal government; it was also carried on in England on a large scale. The object of the political survey was to describe governmental machinery in operation in relation to a precisely specified social milieu.

Another development on the margin of political science was the increasing interest in political geography. This was inevitable, since the new map of Europe was settled partly with reference to the establishment of natural frontiers and ethnic homogeneity. In 1924 the magazine *Geopolitik* was founded in Germany by Karl Haushofer, and still earlier an attempt was made by Rudolf Kjellén in Sweden to incorporate political geography into descriptive political science.

If it is true that political science begins where public law leaves off, this period was the first, both for Anglo-Saxon countries and the continent, in which the science came into its own. In spite of the multiplication of written constitutions and of regulatory laws and rules, the drift of thought was distinctly away from the study of structure to a consideration of the realities of functioning. Consequently the dicta of the science became less definite and its dependence upon related disciplines much closer; for the

same reason it was also impregnated with a new vitality and a greater responsiveness to practical needs.

VIII. LAW. The transformation of a system of legal thought in which the will of the state was the central fact into one in which the development of the individual was the primary concern, was the chief accomplishment of juristic activity after the war. This transformation, which had been definitely begun in America just before the war and considerably earlier in Germany, is generally abbreviated as the change from an analytical to a sociological jurisprudence. In terms of this change the varied activities after the war in juristic thought, legal education, social legislation, codification and the reorganization of judicial machinery take on a considerable community of meaning. As a sequel to this change there came a new emphasis and a new perspective in the study of law which lifted it out of its former position as an adjunct to political theory and made of it a complex and ramifying social study.

The opening of the war period found analytical jurisprudence yielding ground in every important juristic system to an invading body of thought which, because of peculiar intellectual traditions and legal-political schemes, was of a different composition in each country. In Germany the decisive influence of Stammler and Ehrlich, operating in a code country, emphasized the need for a dynamic jurisprudence which would continue to adapt a rigid system of law to the changing needs of each period. In France, where the metaphysical tradition had been dominant, distinct trends could be traced toward a revival of natural law, the energetic study of comparative law and the extremist movement for "free law." In England, which had since Hobbes been most intimately allied with the analytical strain of thought, the analytical tradition was most tenacious, giving way only in the historical approaches of Maitland and Vinogradoff. In America a derivative analytical jurisprudence held sway until the vigorous writings of Roscoe Pound and the opinions of Mr. Justice Holmes began to make serious inroads upon it, the first in a direction closely allied to Stammler's sociological school, the latter in the broad spirit of a humanized individualism.

The war itself had an appreciable, although not a determining, effect upon subsequent juristic developments. It produced a prolific literature of international law, in which the

fundamental concepts of sovereignty, nationality and neutrality were reexamined. Considerable creative activity went into the organization of the judicial machinery and the analysis of the juristic theories that were to govern the outlawry of war and the effective arbitration of disputes. The new constitutions of the post-war European states brought with them the problems of adjusting theories of public law to a conception of powers derived from a written constitution, and stimulated a revival of analytical jurisprudence; an impulse in the same direction came from the quest of stability in an era of rapid change. The unprecedented activity in constitution making also presented an opportunity for a fresh examination by continental jurists of Anglo-American legal institutions, particularly the American doctrine of judicial review of legislative acts, which the Reichsgericht in Germany adopted. In England the war, among other factors, gave an impulse to the process of transforming empire into commonwealth which was accompanied by an attempt to clarify the status and legal relations of the constituent political units.

But these direct results of the war were the incidental rather than the essential lines of advance along which legal theory developed. The principal single force behind this development was the actual character and functioning of legal institutions in this period. Just as the primary concern of law in the Middle Ages was the proper ordering of one's religious life, and in the early modern period the building up of effective legal control by the central government, so it came in this period to be the smooth dispatch of intricate business relations, the maintenance of property rights, the protection of the individual in large and impersonal communities. The refinements of the corporate organization of the business unit, the fluidity of credit transactions, the complexities of financial organization illustrate the demands that business made on legal machinery and concepts. The history of the relations of government and public utilities in the American legal situation is an indication of the concern of American constitutional law with property rights; and the frequency of crime commissions testifies to the importance of the problem of criminal law and administration in a large city. Juristic concepts, legal education and judicial machinery had to be refashioned to meet these compelling demands with some degree of adequacy, and that process subsumed most of juristic attention after the war.

In this transformation the governing intellectual principle was that of pragmatism. This was especially true of legal development in America where Mr. Justice Holmes, in his famous remark that "the life of the law is not logic but experience," not only expressed a personal conviction but caught the increasingly characteristic note of American jurisprudence. This tendency had already shown itself in England before the war in the work of Pollock and Maitland, who had qualified Austin to the extent of defining law as "the sum of the rules administered by courts of justice"; a realistic examination showed that under a common law system the center of gravity was not the single creative act of the legislator but the continuous series of creative interpretations by the judge in the daily stress of court business. But the most insistent application of this pragmatic attitude was found in America, where the moving power behind legal change was the Supreme Court and where not only the interpretation but even the validity under the constitution of certain crucial laws were not known until the Supreme Court had passed on a case involving them. The attitude is illustrated in such varied features of the American legal landscape as the use of the case system in legal education; the conception of law as an entity which does not at any moment exist except in the probability of its application to the specific set of facts involved in the next case and, as a consequence, the opposition to such judicial machinery as advisory opinions on the ground that they postulate the existence of a legal principle abstracted from a particular set of facts; the consciousness of the evasive and indefinable character of legal concepts, such as due process, which was revealed in the writing and teaching of diverse but representative American legal scholars like Cook, Frankfurter, Powell and Hamilton; the increasing practise of adjudicating a case not by the method of abstract logic but in the context of social arrangements that give it significance and, as a result, the transformation of the legal brief and sometimes the judicial opinion into an economic or sociological treatise.

The vigorous and able thinking that characterized the opinions of the American Supreme Court was one of the outstanding juristic achievements of the period. Although the form and purpose of an opinion are completely alien to the deliberate grappling with jural concepts to be found in the treatises of system builders like Austin, Kohler, Stammler or Géný, these opinions may be said to have added to the recognized

schools of jurisprudence a characteristically American accession. Their principal ingredients, with some admixture of ethical and historical points of view, were the traditional American stress on individualism and the desire of the sociological jurist to apply law in the context of a changing society. Opinions of this kind were particularly characteristic of Mr. Justice Holmes and Mr. Justice Brandeis, although in strikingly diverse proportions. Two such apparently antithetical attitudes would seem strange partners, and it is true that Mr. Justice Holmes when, at times, he found the two in conflict rendered exclusive fealty to the first and Mr. Justice Brandeis to the second. But in their judicial opinions and also in the main trend of the court's decisions during this period there was evidenced a remarkable attempt to weigh the conflicting demands of social policy and individual values. The central problem of law became that of so controlling the growth of legal institutions as to make for the best development of the individual in society.

To make such an attempt with even a partial degree of success was a heroic procedure. For a body such as the Supreme Court, so situated in the American political scheme that its decisions could affect the future course of social legislation or deflect prosperity from one channel of business or section of the country to another, the process of decision became an adventure in statesmanship. American constitutional law, although in the controversy over prohibition and civil liberties it continued its traditional preoccupation with the Bill of Rights, in dealing with the more vital questions became increasingly absorbed with the legal bases of the economic and social system of the most highly industrialized country in the world. How perilous a responsibility this imposed upon the judiciary was stated with engaging clarity by Mr. Justice Cardozo in *The Nature of the Judicial Process* (1922).

The wide acquaintance with continental law and juristic literature evidenced in this book is representative also of the movement toward what may be termed a "reception" of European legal thought. Pound, in support of his plea for a sociological jurisprudence, and Wigmore, with a primary interest in comparative law, introduced American scholars to the significance and content of the principal trends in European jurisprudence. The *Continental Legal History Series* and the *Modern Legal Philosophy Series* did much to attenuate American legal provin-

cialism. But such an interest cannot with truth be said to have taken deep root in America, and the increased interest in Anglo-American law which scholars on the continent began to evince was sporadic and undetermined. In another direction a controversy which had started with *éclat* and promised to have revolutionary effects burned itself out in an uncongenial atmosphere. The furor with which Wesley Hohfeld's criticism of the existing terminology of jural relations was received, and the degree to which his scheme for clarifying and classifying them dominated for a short period the teaching at the Yale Law School, were perhaps an indication of a current belief that more than of social consciences judges stood in need of sharper wits. After a heated controversy between Walter Wheeler Cook, the principal Hohfeldian exponent, and Albert Kocourek, who while sharing Hohfeld's interest in jural analysis set up a rival scheme, the issue cooled. It was probably less suited to the case law system in America than it might have been to the civil law system on the continent, where the necessity for formulating law constantly on the basis of a written text made an underlying scheme of jural relations desirable. Its principal significance became finally its influence on Cook who, adding to it the findings of the New Physics and the New Logic, broadened it into an investigation of the scientific method in law; and on Commons, who used an adaptation of the Hohfeldian system in his *Legal Foundations of Capitalism* (1924).

Taking issue forcefully with the categorizing of the legal analysts, the sociological school, with adherents in every country and with Stammler and Pound as its principal leaders, established the dominating trend in juristic thought. It spent much of its early force in a frontal attack upon the intrenchments of "mechanical" jurisprudence, in the violence of which it sometimes exposed itself to attack on account of the extreme formulation of its stand. In its more constructive phases it revolutionized the study of law, leaving its most appreciable mark on legal education, research and reform. In America it was connected with every important movement in these fields.

In legal education the case method reached the apogee of its influence in this period, and there were even rumblings of a revolt against it. This revolt did not advocate a reversion to the textbook method but aimed at making the study of a case merely a point of departure for

an excursion into the social and philosophical problems of which it formed the end product. This represented, although in an extreme form, a tendency which the innovators in legal education manifested throughout the period—that of paying increasingly less attention to the professional aspects of legal education and of using it to transform law into a social study. The reorganization of the curriculum on a functional basis, which absorbed much of the administrative energies of the principal law schools, was built on a fundamentally sociological conception of the functional role of legal rules and institutions in society. When the disparity between the aims of professional legal education and the social study of law became increasingly clear, the two activities were differentiated and the latter was organized definitely as research, sometimes with a separate staff and predominantly by the method of group collaboration.

Whatever the degree of success with which the fruits of legal research justified its pretensions, there can be little doubt that it was a valuable auxiliary in the movements for clarification of legal rules and overhauling of judicial machinery. The work of the American Law Institute, the revision of the Code of Civil Procedure in Germany, the reform of the judicial organization in France and Ferri's unsuccessful attempt at a thoroughgoing reform of the Penal Code in Italy were inspired and conducted by legal scholars in the light of what they considered the latest research. The early hope of Pound that legal scholarship might prove eventually effective in social engineering found ample realization when the jurist was called in, as the engineer might have been, for a survey of a troublesome problem. With a note of authority the jurist as expert suggested remedies in the case of the breakdown of the machinery of criminal administration (Cleveland Crime Survey); the congestion of the nation's business in the Supreme Court (Frankfurter and Landis, *The Business of the Supreme Court*, 1927); the unnecessary litigation of commercial disagreements (the movement for commercial arbitration); the non-enforcement of the prohibition laws (President Hoover's advisory committee on law enforcement).

The obvious social context of every legal problem and the building up of a system of legal research and study to deal with the problem adequately in this context served as the connecting links between law and what lawyers began to call "the other social sciences." In these

interrelationships lay the claim of law to be considered a social study. In the investigation of the origin and development of legal institutions and concepts only a beginning was made in this period, but enough to show that here the genetic method was successful in revealing "the dead hand of the past" and the devious and amazing carry-over of old ideas to deal with new situations. No more fertile phase of intellectual history was to be found in any of the social sciences. The study of non-political groups and associations, as they had been clarified in sociology, yielded, in the pluralistic theories of Duguit, Krabbe and Laski, a revolutionary change in the political-legal concept of the state, and had correspondingly important consequences for the theory of the nature of law. The studies by lawyers and economists of the legal foundations and the legal scaffolding of the two principal institutions that have emerged into dominance in modern society—property and contract—contained much dynamite for accepted attitudes in both law and economics. Social work carried its activities over into the field of law, and considerable interest was stirred up over the small claims court, legal aid and the juvenile court. Anthropologists (Lowie, *Primitive Society*, 1920; Malinowski, *Crime and Custom in Savage Society*, 1926) grappled with the problem of legal organization in the primitive community and clarified the functional relationship between the legal system and the social organization. Psychology with its revolutionary though somewhat unstable revaluations undermined the substructure on which the elaborate system of legal evidence had been built. All along the frontiers of law there was a good deal of stir. If there was too much faith in the results of group research and in the genuine synthesis that might be effected by the juxtaposition of law with another social study, it was merely a sign that one of the oldest of organized studies was passing through a new youthful phase.

IX. HISTORY. In a group of social studies prolific in innovation the peculiar propriety which seems to stamp the adjective in the phrase "the new history" is of considerable significance. It presents the paradox that the study which has from within itself generated the least of actual novelty offers the appearance of the most radical transformation. And it points in partial explanation to an articulateness and a militancy on the part of the spokesmen for

history that transcend the revivalist spirit of the other social sciences.

The movement for a new history, although in the swing of it there was an accelerated swiftness after the first decade of the century, did not come with entire suddenness. Behind it there was in each country an evolution of historical writing in which sporadic beginnings of the later tendencies can be distinctly traced. In Germany, side by side with the efforts toward the crystallization of history into an exact science, there may be discerned a movement for the broadening and humanizing of historical writing. From the *Kulturgeschichte* of the late eighteenth century this tendency can be traced through the nationalistic and idealistic trends of the nineteenth and the methodological clash that centered around Lamprecht. Defeated and deflected until the war, the impulses behind cultural history found renewed expression in the general revulsion against *Macht-politik* that followed the German war experience. The dominant historical interest therefore became *Geistesgeschichte*, a peculiarly German variant of the new history, a transcendental study of a culture with the intention of finding the spiritual realities underlying political and economic forms. In France an unusual activity during the nineteenth century in the history of ideas and in archaeology and geography was the significant precursor of Henri Berr's declaration of the aims of synthetic history in his *La synthèse en histoire* (1911). The work of Berr and his associates on the *Revue de synthèse historique* was finally productive of a conception of world history which they proceeded to apply in *L'évolution de l'humanité*, a series impressive for the range of human activity it treats and the important contemporary institutions whose history it develops, as well as for its emphasis on what was formerly known as pre-history. In England, where the historical tradition had always been so dominantly one of narrative grace and psychological penetration, unaided by any intimate connection with the social sciences, and where therefore Buckle had been a phenomenon and Green an episode, it was not to be expected that the new history would find fertile soil. The work of F. S. Marvin, with his conception of the "living past" as a dynamic factor in the present, and his conviction of a unity which underlies the varied manifestations of a period, represented, however, a break with the tradition. That it represented also a genuine change in the demands of readers is shown by

the success of H. G. Wells' brilliant and daring survey of world history, *The Outline of History*, which seems largely to have been influenced by Marvin's ideas.

It was in America, however, that the ideals of the new history received their most articulate expression. McMaster's emphasis on the life of the common man, like Green's work in England, had represented a break with the tradition. And when F. J. Turner, in the tradition of Buckle, advanced an anthropogeographical theory of the influence of the frontier, the reception it received proved not alone the fertility of the idea but even more the poverty of American historians in interpretative leads. But the principal stir in the American historical movement did not come until just before the war, and then, somewhat strangely, from scholars in the field of European history. The prime agitator was James Harvey Robinson who at Pennsylvania and later at Columbia effected an atmosphere of vitality such as American historiography had not experienced since the return of American students from the seminars of German scientific history in the eighties. His book, *The New History* (1912), which represented also the credo of the group associated with him, called upon historical writing to encompass the entire breadth of man's activities and to treat the past dynamically as the mold from which the present has been cast. For such an intent the field of European history was especially adapted. It offered rich material for what Robinson was aiming at—intellectual history, the portrayal of the succession of widespread intellectual attitudes in Europe at successive periods and their survival in the contemporary consciousness of the western world. Despite wide divergence of emphasis on other scores, a common interest in this theme gave an essential similarity of temper to the work of Haskins, Schevill, Shepherd, Hayes, Cheyney and Thompson.

The new historical approach, once it had penetrated American scholarship, was applied with the greatest success to the study of the American past. The *Chronicles of America* (1918-21), edited by Allen Johnson in fifty volumes, and containing significant work by Becker, Dodd and Andrews, represented a considerable degree of success in absorbing the interpretative leads deriving from the other social sciences. Schlesinger's *New Viewpoints in American History* (1922) may be taken as a summary of the changes in the historian's horizon which the lapse of a decade since the publi-

cation of Robinson's book had produced. In the decade that followed Schlesinger's work this changing outlook found even more prolific expression. James Truslow Adams in a three volume survey of the sectional history of New England dealt in the approved manner of synthetic history with the important phases of New England life and thought. Lewis Mumford in *Sticks and Stones* (1924) and *The Golden Day* (1926) sketched in broad strokes the main outlines of American intellectual history, as revealed through American architecture, literature and philosophy. An impressive survey of the entire range of American thought, in which the standards used in evaluating particular personalities were those of the social theorist rather than the literary critic, was contained in Vernon Parrington's *Main Currents in American Thought* (1927-). Charles and Mary Beard, in their *The Rise of American Civilization* (1927), capped their previous monographs on the economic aspects of American history by sketching deftly and brilliantly the forces that went into the building up of a culture. *A History of American Life*, planned in twelve volumes and edited by A. M. Schlesinger and D. R. Fox, is "social history" in that it places its emphasis on the daily life of the undistinguished masses rather than on the careers of the famous or talented.

This swing of the movement for a new history indicates an inescapable contagion in the idea; varying national traditions and varying academic groups responded to it in their own fashions. An individuality might perhaps be given to each of these different manifestations, but a sharp distinction between them would define them out of recognition. Beneath the variety of forms there was a community of viewpoint which showed them to be merely variants of a central idea. The apparently common element was rebellion against the narrowness of the historical outlook, and the meagerness of the sources from which historians were deriving their ideas. To say that the program of the new history called for an extension of the boundaries that hedged history about is too mild; it was rather a removal of all boundaries. The agitators for a new history refused, like Terence, to admit that anything human was alien to them. Starting with the postulate that history was everything that could be known or found about the past, they were by a relentless logic forced into an unenviable position of omniscience and omnicompetence. Refusing to admit that historiography took its

point of departure from written records, they had to insist that it took all time for its sphere and so were compelled to become amateur archaeologists, anthropologists, cosmologists. Once they denied that political history was the peculiar field of the historian they could find no stopping point until they had added every other sphere of social activity; and they were compelled to become amateur economists, sociologists and literary critics, as they had once been statesmen, generals and theologians. They evolved thus a program which called upon the historian to encompass the whole of life, to portray the moving stream of cultural development.

To support this changed attitude there was an influx of new factual material which, whether it preceded or followed the interpretative leads, was certainly indispensable in establishing the new history on a firm basis. The controversy over war guilt unloosed a flood of memoirs and opened the archives of several governments. The revolutions in Russia and Germany converted the opening of the archives in those countries into gestures for the renunciation of the old autocratic regimes. Diplomatic history and the realities of statecraft behind diplomacy dominated for a time the historical scene. New research techniques, more adequate library facilities for the scholar, the increase of publications in monograph and periodical form, the multiplication of guides and bibliographies, the historical researches carried on in the wake of the development of historical interests in the other social sciences—all of these combined to enrich the materials with which history worked.

But the principal impulse in this direction came from archaeological advance. Troy, Mycenae, Cnossus and Luxor had been for an earlier generation the symbols of an antiquity beyond that of written records which nevertheless was considered within the scope of history; and historians had been stirred by the archaeologist's dream of reconstructing a civilization with the aid of a few shards and urns and deductive logic. But the unearthing of buried cities proceeded at a pace and on a scale that made the old term "classical antiquities" a bit antiquated and, when historians began to show interest in discoveries which did not involve the gleaming columns of temples but flints and iron implements, it was evident that they had ceased to regard archaeology as principally an adjunct to classical studies but valued it for the shift in perspective that it compelled. In the new time

perspective antiquity was more closely associated with the early geologic epochs than it was with the invasion of the Dorians or the founding of Rome; and the term pre-history lost any meaning it may originally have had. Similarly the ethnological literature, always ignored by historians because it dealt with peoples who had not entered into the stream of western culture, became something that had to be taken account of. If the western peoples were only an episode in the sweep of world history, then they were also only a section of the geographical span of culture. The Bushman and the Melanesian as well as the Frenchman and the Englishman became part of the historian's subject matter, and the accumulated material on their history became part of the storehouse of facts on which the historian depended.

For historians of the established faith, who believed that the line of historical advance lay in the increasing accumulation of facts, this influx of material from archaeology and anthropology, from archives and business records and population and wage statistics, seemed a sound and sufficient basis for the expansion of history. Some of them were even beguiled by this into a hesitating acceptance of the tenets of the "new history." But to historians possessed of less faith in the unaided sufficiency of "facts" the line of advance lay rather in the possibility of fresh interpretation of such facts as were at any time available. In their view the facts of history—its material—lay all around for potential mining, embedded in the past, waiting only the impulse to explore that particular vein. And—such were the devious ways of historical advance—such an impulse could come only from the awakening of new intellectual curiosities whether arising spontaneously in the mind of the historian or relayed to him from outside, or from the insistence of new problems demanding to be traced back into the past. The amazing consciousness which the generation possessed of its dominant contemporary institutions, ideas and problems sent historians back in the most fruitful of their researches in a quest for the origin and development of these institutions and ideas.

The interpretation of historic facts that the historian of the old accredited faiths recognized as valid was the appraisal of their authenticity. All the energies of the "scientific" school of history were directed toward the building up of a critical body of rules of evidence, much like the rules of evidence in courts of law. Of course

all rules of evidence, legal and historical, since they concern themselves with the ascertainment through the medium of human testimony of the authenticity of certain events, become antiquated when the psychological surmises as to the degree to which a man's statement can be believed become antiquated. The old psychology of historical evidence, like that of legal evidence, was somewhat over-simple in its assumptions and was disintegrating slowly before the recognition of the intricacies of the new psychological viewpoints.

The problem of historical evidence agitated the scientific historian because rigorous rules encased him in an *aes triplex* in his quest for certainty and objectivity. The same problem furnished for some of the new historians the starting point for an interesting revolution in attitude. Finding in their studies what was not entirely apparent before the newer psychological developments—that different men will see exactly the same event and will record quite different versions—they were led to a suspicion of the science of history. It was impressed on them, as it could not have been impressed on any others in the social studies except the psychologists, that men's minds move covertly toward devious and surprising conclusions and that the narrative of two historians of the storming of the Bastille may, like the account of two eyewitnesses, be almost completely antithetical because colored by their preconceptions. The propaganda activities of historians during the World War served to bring out even more clearly the nature of the historiographic process. There arose therefore among some historians a significant awareness of the preconceptions with which they approached the raw material of history.

Such a development was of course fatal to the long established self-sufficiency of historians—their independence of any surrounding social disciplines. The buttress of this self-sufficiency had always been the belief that the facts spoke for themselves. But when the same fact was two different things to two different persons it was obvious that if it spoke for itself it did so in a language that could be variously translated. Everything then broke down. Historians saw that even in the past when history had remained aloof from any alliance with the social sciences, it had used interpretations but had not been conscious of them. The interpretative equipment of a political historian had been mainly an individual psychology involving the ambition, cruelty and effeminacy of emperors, a

crude social psychology built around the demagogue and the mob, and a repertory of political ideals such as liberty and religious tolerance. Historians began to feel that if interpretative leads were inevitable it was better to apply them deliberately rather than in haphazard fashion, and to draw them from the entire range of the social sciences rather than merely from political theory.

This connection between the new history and the social sciences is one that was considerably stressed in commentaries on the new history. It found its most explicit and insistent expression in the writings of H. E. Barnes (*The New History and the Social Studies*, 1925; *History and Social Intelligence*, 1926). The connection was a genuine and significant one. The development of the older social sciences—politics, economics, jurisprudence, sociology—to a place where their formulations became well established, and the rise of such new disciplines as cultural anthropology, human geography and social biology had considerable relevance for history; they emphasized the richness of the material to be treated in the non-political aspects of life and they made it impossible for the historian to neglect the interpretative leads they offered. Each of these social sciences, before historians became fully aware of its significance, had built up a historical literature of its own. The assimilation of these historical treatments of whole sections of the life of society which had formerly been somewhat alien to the province of history was in itself an educative process of considerable consequence for the historian.

A summary review of the interpretative leads which history borrowed from the social sciences would show that social biologists, through the Darwinian hypothesis, introduced the concept of evolution, and the race theorists the rather risky interpretation of national development in terms of racial endowment; that the anthropologists thoroughly imbued the historian with the concept of culture and directed him to the study of the totality of the life of the community; that the anthropologists and archaeologists radically changed his perspective in time and space; that the geographers gave him an environmentalist interpretation running in terms of the inexorable elements which constitute the physical landscape and the complex accessions which constitute the cultural landscape; that the psychologists affected his con-

ception of the inner springs of motive and emotion underlying the actions of the "men who made history"; that the collectivist psychologists drew his attention to the fundamental role of the masses and the common man in history; that the economists pointed out the dominance of the maintenance problem in community life; that the political scientists showed the realities behind governmental structures and the propulsive force of such political aspirations as those for nationalism and later for internationalism; that the sociologists worked out a set of conceptions of the realities of group life which enabled the historian to separate the formerly undifferentiated "nation" or "public" into its various racial, economic and interest groups and to trace the entrance and role of each in the life of the community.

When history is thus seen as an omnivorous borrower it becomes clear that the pother about making it keep pace with the social sciences was a matter of primarily educational concern. Although there are other social studies which perform a synthesizing function they do so rather for the social scientist than for the layman. History has always been a common carrier, the accredited vehicle for transmitting to the lay reader as much of the philosophy of society as historical scholarship is able to absorb. Being primarily a narrative of the past it is, from the combination of literary finish and scholarly substance of which it is susceptible, pleasanter to read and easier to teach than the more analytical social sciences such as economics and sociology. There had always been a lag between the contemporary state of the "moral sciences" and their reflection in historical writing, but as long as the connection between the two was not clearly seen no great stir was raised. The consciousness of this connection, when it came, was converted into a considerable *malaise* when the social sciences developed so rapidly as to make the gap between them and history a precipitous chasm. For it seemed disastrous to those historians who were conscious of the educational responsibilities of their craft that these duties should be so grossly shirked. To them the "new history" offered the opportunity of modernization so that their task of interpreting the past of society might be performed in the light of the latest researches on the phases of social organization.

So great a degree of methodological activity could not proceed unscathed by the ultimate questions of a philosophy of history. The moot

problem of historical interpretation—that of the great man theory against historical determinism—received a fresh impetus from the subtilizing of the economic interpretation and from the psychoanalytic approach to biography. The cyclical theories of historical development, which in the previous generation had so brilliant a protagonist in Henry Adams, cropped up in a new form in Spengler. Croce gained considerable adherence to an essentially idealistic scheme of interpretation. But the actual writing of history went on, affected much more by the general intellectual character of the age than by this continued system building. It has often been pointed out that each age rewrites its history in accordance with its own preconceptions. Ours would seem to be, in an age dominated by science, an inveterate interest in and reliance upon causality, interrelationship of parts and biological growth and, in the post-war period of psychology and pragmatism, an emphasis on the realities behind the rhetoric of events. From this confusion of trends there emerged the "new historian" who, at his best, whatever the novelty of his jargon and the strangeness of his affiliations, retained the essential historical endowment of narrative power and charm, and a mordancy about human motives.

X. INTERRELATIONS. In a period of such rapid development for each of the social sciences the hegemony over the whole field could not be arrogated by any one of them. Efforts had been made in a previous period to build up a single science which would synthesize and eventually absorb the others. But the failure of this attempt where it had been most hopeful, in sociology, marked what was probably the climax of such efforts. A trend set in toward differentiation rather than synthesis. New sciences emerged, immature ones grew to maturity, studies were organized that acknowledged no sovereignty and knew no boundaries. In place of an ideal of imperialistic unity was substituted one of autonomy combined with the highest degree of intercommunication and fluidity of borrowings.

The group of studies that stood in this relationship came ever more surely to be known as "the social sciences." In the term there was conveyed the notion of a variety of interests bearing a kinship to one another, all of them concerned with the study of society and united by a similarity of interest and a community of methods in treating their common subject

matter. In university administration, learned society organization and popular consciousness there were growing indications of the acceptance of this notion of a unity in the social sciences. Specific incidents in this development were the formation of the Social Science Research Council, the organization of university departments and curricula, of research projects and foundations around the idea of a group of social studies, and the publication of symposia such as *The History and Prospects of the Social Sciences*, edited by H. E. Barnes (1925), *Recent Developments in the Social Sciences*, edited by E. C. Hayes (1927), *The Social Sciences and Their Interrelations*, edited by W. F. Ogburn and A. A. Goldenweiser (1927) and *Research in the Social Sciences*, edited by Wilson Gee (1929). As an item in the same process may be cited the launching of the present undertaking, with its intention of making available the combined viewpoints of all of the social sciences on the important social ideas, institutions or practises of the modern world.

This concept of the "social sciences" was obviously based on an analogy with the group of natural sciences. It met the need for opposing to the studies that dealt with matter a comparable group dealing with man and his activities. Not entirely negligible in this connection was the fact that such a rubric suited the convenience of university administration. But the most persuasive attribute of the phrase was the hint of certainties that it conveyed. It offered a warrant of the progress which these studies had already made toward the ideal of the natural sciences and an earnest of faithful intention to traverse the remainder of the distance. Those who disbelieved in the possibility or the desirability of such a rapprochement sought solace in the reflection that the adjective "social" qualified all harm out of the noun. Others, as they watched the certitude even of the natural sciences disintegrating before the new researches, accepted the term "sciences" as carrying with it no invidious superiorities but signifying only a body of knowledge, as did the German *Wissenschaften*.

The establishment of the group of social sciences as a definite entity made impossible on the part of any one of them an impulse for splendid isolation. The jealous maintenance of boundaries that had characterized the previous period had carried with it the belief that there was a province of fact in which all sciences but one were aliens. In terms of this belief the

principal task for that science was to delimit its scope and within that scope to clarify its concepts. But such a procedure, although conducive to precision, did not provide the continuous stimulation that comes from borrowings. The distinctive and fruitful results in the post-war period proceeded rather from the frequent foraging expeditions that crossed the boundaries from one science to another in search of whatever served their curiosities, or from the exploration of tracts which the previous delimitation of scope had left neglected.

Implied in this tendency was the view that each social science dealt rather with a phase of all human activity than with some definable portion of it. What distinguished one science from another in this view was not the possession of an exclusive range of material but the application to the common body of material of the method or "slant" which each had developed and which, it was hoped, would yield significances hitherto unrecognized. The family, for example, was a subject to which no one social science could any longer lay exclusive claim. Studied by the social biologist, anthropologist, psychologist, economist, political theorist, jurist, historian, educationist and social worker, it showed a different facet to the interest and approach of each. No adequate understanding of the nature of the family and no balanced appraisal of its social role could be formed by using the technique of a single science.

The divisions between the sciences, therefore, while retaining their significance as designations of the distinctive interest and approach of each, became irrelevant as actual working rules. If a problem was to be analyzed or an institution studied, its ramifications into every phase of activity defeated the boundaries of the sciences. The dominant trend became one of integration. Through group research an attempt was made to reconcile the apparently conflicting demands of specialism and totality of view. Where versatility lent courage the lone investigator followed his subject in its precarious trajectory through the realms of social science. More often the juxtaposition of intensive studies by several specialists was counted upon, with a blind faith, to result of itself in integration.

The greater interest, characteristic of a period of reconstruction, in the harnessing of research to the solution of immediate problems was only one element in the new situation. Equally important were the movements within each science in reaction to the formalism of the previous

period. The attempt to break old patterns was linked with the introduction of fresh thought from the outside. Often the ideas which were borrowed, as was evidenced when the economics of industrial relations strove to make use of the instinct hypothesis of the new psychology, were those whose viability even in their original habitat had not been tested. But the "borrowing" continued and added considerable richness to the social-scientific thought of the period. Facts, hypotheses, points of view and interpretative leads passed from one science to another.

This borrowing and the considerable influence exercised upon all of the social sciences by the prevailing intellectual mood of the period may account for the community of method that they possessed. The reliance upon the quantitative method characterized all of them and laid its imprint upon the period more deeply than any other approach. At the other extreme a method which became known as "institutionalism" and penetrated into economics, history, sociology, social psychology and law, emphasized the broad consequences of fundamental

social structures of idea and practise. "Functionalism" studied the essential role of any activity in its setting of social organization. The idea of the mastery of the social process by society, known variously as "social control" and "social engineering," turned the activity of practically every discipline in the direction of the application of its precepts. "Regionalism" brought with it the emphasis on the geographical unit of study which would yield actualities instead of hypotheses and could in the form of field study be encompassed at first hand by the observer. Configurationism in its varied forms made the task of each science at once more complex and more dynamic.

Throughout their range the social sciences showed evidences of the instability as well as the intellectual stir that accompany the contact and borrowing of ideas. They blurred rather than sharpened the outlines of their conceptions, and they did not capture immediate certainties. But they were storing up a vitality which would tide them over any lean years that might lie ahead.

EDITORIAL STAFF

INTRODUCTION: PART TWO

The Social Sciences as Disciplines

I

Great Britain

The outstanding feature of the development of the social sciences as disciplines in Great Britain is the lateness of their inclusion in the educational system. Despite apparently promising developments in Scotland in the eighteenth century and the foundation of a number of chairs in England and Ireland in the early nineteenth century, a special committee of the British Association for the Advancement of Science reported in 1894 that except at Oxford and Cambridge, where the study was very unsystematic, "it would be difficult to imagine a more complete indifference to the scientific study of economics than that displayed at the present time." Yet economics was then accorded greater academic recognition than any of the other social sciences. Anthropology was not taught in the universities until 1884, and sociology not until 1904. Political science had long been taught with varying effectiveness in connection with philosophy, but no chairs were created until the twentieth century. Modern history was studied very little at the universities until after 1850, and not until the end of the century was much attention paid to its social or economic aspects. Law has until recently been taught entirely as a professional or technical subject; in 1924 the Downing Professor at Cambridge claimed that in seven centuries of law teaching "the last fifteen years stands out in bold relief as a period of notable progress." Even today, except in London, the social sciences occupy the smallest, least popular, and least well-endowed position among all the subjects at the different universities, and they can scarcely be said to have penetrated the pre-university educational system.

I. THE UNIVERSITIES. This late academic development and subordinate position of the social sciences is not easily explained. British scientists made distinguished contributions to the social sciences during the nineteenth century. These sciences were systematically studied in foreign universities, where they had been an integral part of the educational system and attracted many and brilliant students. Even in Great Britain a host of learned societies actively

promoted their study outside university walls. Some explanation of the backwardness of universities may be found in the uncertainty as to the scope and content of the social sciences and as to their relation to the already accepted subjects of study, and in the lack of textbooks—explanations of singular relevance in relation to the position of the teaching of anthropology and sociology. The teaching of economics has been hampered, in addition, by allegations as to its identity with political propaganda.

Peculiar historical factors in British educational theory and development yield a more far reaching explanation. Until almost the end of the nineteenth century Oxford, Cambridge and London were the only English universities and, as far as educational policy was concerned, London was insignificant. The overwhelming social and educational prestige of Oxford and Cambridge led other universities, as they developed, in the direction of the educational ideals of the two older universities. Until the reforms of the Commission of 1852 were carried out, the colleges at Oxford and Cambridge were predominant; the universities were concerned only with conferring degrees, and the professors had little place in the university system. The first duty of the student was to attend college lectures and classes and to prepare for examinations over which the professors had little or no control. Attendance at professorial lectures was an indulgence by the student, and departure by the professors from the narrow field of textual commentary, or the introduction of subjects not bearing directly upon examination requirements, was fatal to the maintenance of an audience. The mere appointment of professors in the new sciences therefore availed nothing. The real problem was to embody the subjects in the examination syllabi.

From this point of view it was particularly unfortunate that the earlier chairs in the social sciences were frequently either tenable for a limited period of time, or so poorly endowed that their occupants were unable to concentrate upon securing a place for their subjects in the examination syllabus or even upon developing their science.

They were first of all government officials, lawyers, public men, or judges, and professors only in their spare time. Even in the latter part of the nineteenth century, when full time and adequately endowed chairs became more common, the old tradition, combined with the practical closeness of the connection between the social sciences and political or social life, led many professors to desert the classrooms more or less permanently for public life. This slow development of an academic social science profession has resulted in a relative paucity of good texts written by teachers.

All attempts to embody the new sciences in the university curricula met with great opposition. The older universities had always insisted that it was their function "to train the powers of the mind, not to give much positive or any professional knowledge." Supporters of the social sciences had therefore to demonstrate, first, that their subjects were not professional (as Blackstone's introductory lectures indicate, even English law was suspect) and, second, that as a training for the mind they were equal to the classics or to mathematics. The normal course for honors in most English colleges provides for at least one year of general education, followed by one or two years' specialization in the field in which the candidate has elected to study for honors. The first task of the advocates of the social sciences was thus to secure a place for them among the subjects which might be studied for honors. In the face of great opposition Whewell carried through the institution of a Moral Science Tripos at Cambridge in 1848, in which for the first time it was possible to pursue an honors course in moral philosophy, political economy, modern history, general jurisprudence and the laws of England. Two years later a school of law and modern history was created at Oxford as one of four schools which could be taken for the final honors degree. But the scope of the two new honors groups proved too broad to be popular. Simplifications were introduced at Cambridge after 1860, including the creation of a History Tripos in 1873, while at Oxford both history and jurisprudence were made into separate schools in 1872. Although the new schools attracted increasing numbers of students they paid little attention to the social sciences. Even the Moral Science Tripos at Cambridge, which recognized these sciences more completely, failed to attract more than a handful of students because of its heavy philosophy requirements. Nor were these handicaps in

the study of the social sciences eliminated by the creation of the Economics Tripos at Cambridge in 1903 or the Oxford Final Honours School of Philosophy, Politics and Economics in 1922. For, especially at Oxford, the preliminary examinations prior to final specialization involved so much attention to classics and either mathematics or logic that there was a strong temptation to continue in those fields rather than to attack what was virtually a new subject. Even today these disabilities of the social sciences have been but partially overcome.

Similar influences were at work in the other universities in Great Britain. The difficulty of persuading students to take the social sciences as subjects for an honors degree in arts or science, in the face of the usual enforced preliminary study of other subjects, ultimately resulted in the creation of special degrees in economics, commerce or administration in which the student concentrated for three years on various aspects of the social sciences. The creation of special degrees for the social sciences commenced in London in 1899, and most of the other universities, except Oxford and Cambridge, have now followed suit. Occasionally the sciences are not studied during undergraduate years but can be taken for a special diploma or certificate.

But the eventual embodiment of the social sciences in the university curricula and the removal of the requirement of a long preliminary study of the old established disciplines failed to overcome the greatest hindrance to their academic development, namely the tremendous and disproportionate prestige attaching to high honors in classics or mathematics. This extraordinary prestige of the older studies has been strengthened by the fact that university prizes, entrance scholarships and fellowships were long offered in these subjects alone. To study the social sciences was therefore to be doubly penalized: first, by selecting a field which had little academic status and, secondly, by being automatically barred from competing for public prizes. The efforts of enthusiastic benefactors in the last seventy years have failed to overcome the endowment of centuries and, except in London, the social sciences remain but poorly endowed in comparison with other branches of study. Consequently during the nineteenth century brilliant men rarely sacrificed their chances of distinction by embracing the study of the social sciences, and even today the best men, at least at Oxford and Cambridge, tend to specialize in

them only after they have achieved the desired distinction in the subjects that carry prestige.

Even the practical utility of some of the social sciences failed to stimulate their study. That a demand for men trained in the social sciences did not come in Great Britain, as it came elsewhere, from the legal profession and from the civil service, can be explained only by reference to traditional attitudes and historical accidents. Although in the thirteenth century Oxford was an important training center for lawyers, the gradual supersession of civil and canon law by common law in the centuries that followed caused the center of law teaching to shift from the universities to the schools of law attached to the courts in London. By the beginning of the nineteenth century the London schools had relinquished all teaching and the student of law acquired his knowledge empirically as a pupil in the offices of a practising lawyer. Despite the organization of teaching by the Incorporated Law Society (for solicitors) in 1833 and by the Council of Legal Education (for barristers) in 1852, both societies have adopted a narrow view of the training required for the profession. Not only has their own teaching been severely practical as a general rule, but they have also regarded the training given by the universities as altogether too theoretical to form a preparation for professional practise. Except for relatively unimportant and recent exceptions, they have refused to grant exemptions from their own examination and training requirements to holders of university degrees in law. Any development of the study of the wider aspects of law as a social science, rather than as a set of professional rules, has therefore taken place not because, but in spite of, the requirements of those who control entry to the profession. Even in Scotland, where famous schools of law existed in the eighteenth century, the two branches of the legal profession required attendance, if at all, merely at the more technical courses, and the audiences of the classes in Roman law or jurisprudence consisted largely of individual practising lawyers who took a more liberal view of their professional interests.

The British civil service tradition of the adaptable amateur administrator, who can be transferred if necessary from department to department, has created a demand for men with well-trained but not specialized minds. It is thus not a matter for surprise that until after the close of the World War individual social sciences were rated no higher than chemistry in the allocation

of maximum marks to the various subjects of examination. Only with difficulty did the view prevail that a training in the social sciences might prove an especially appropriate preparation for much of the work of modern government departments. In 1909 and 1913 the Anthropological Institute urged the government to insist upon anthropological training for candidates for the Indian and colonial civil services, but no formal arrangements have ever been made, and the heavy native language requirements of their year of special training has prevented these officers from taking full advantage of the special courses provided for them at Oxford and Cambridge. The recently formed Institute of Public Administration is endeavoring to foster the conception of administration as a unique profession, requiring a special training in which the social sciences shall play a large part.

From the beginning of the twentieth century a new impetus to the study of the social sciences has come from a recognition on the part of an increasing number of employers of the advantages of working with men trained in these disciplines. Thus the Institute of Bankers requires bank clerks taking its examinations to attend courses in economics and banking. Attention is, however, concentrated upon the practical and legal aspects of the subjects. The examinations in the social science subjects held by the professional associations of accountants, actuaries or municipal officials approach the subjects from a similar standpoint. Of more significance has been the increased emphasis upon training in the social sciences as a preparation for commercial life, which was stimulated by a belief in Germany's success in training business men and by the reality of German competition. These views had as their outcome the establishment of faculties of commerce in a number of universities.

In the majority of the universities the commerce degrees have been educational and liberal rather than narrowly vocational in emphasis, and during the two or three years of specialized study the student covers some considerable part of the fields of economic theory, economic history and geography, public administration and theory of industrial organization, as well as more practical subjects such as statistics, accounting or commercial law. The greater part of the purely professional commercial training is provided by "colleges" operated as private enterprises or by evening institutes organized

by public authorities; these have little or no educational status and offer courses narrowly practical in emphasis. Partly, perhaps, because of the wide educational character of the Commerce degree, business men and bankers are still reluctant to afford graduates professional preference, thus diminishing the inducement to the potential student to undertake training.

Schools of social work, more or less closely connected with the universities, have been developed, since the beginning of the twentieth century, for the training of health workers, charity administrators and other social workers. At these schools, of which those in London, Liverpool, Edinburgh and Manchester are perhaps the most important, the elements of economics, statistics, government and social theory are imparted, while advanced courses are occasionally given.

The combined effect of all these influences—the long absence of a full time and adequately endowed teaching staff, the slowness with which the social sciences were formally incorporated into the normal university educational curricula, and the absence of any stimulus from professional quarters—has been to retard the development of social science teaching in the universities. The impetus to their study has always come from outside the universities—from enthusiastic individuals or from the learned societies. It is therefore to be expected that the largest and most comprehensive center for the study of the social sciences should have developed from a specialized institution which was originally outside the university world. The London School of Economics and Political Science, founded in 1895, is today the most important center in Great Britain for the teaching of the social sciences. With a permanent teaching staff of over seventy, representing specialists in all the social sciences; with about half as many occasional lecturers dealing with matters in which they are experts; with a regular student body of between eight and nine hundred sitting for degree examinations and a total student body of over two thousand, it is a symbol of the new importance that has attached to the social sciences in Great Britain since the war. In accordance with the school's claim that the social sciences are in themselves a liberal education, the three years course provided for the B. SC. (economics) degree is very broad. It is a degree in social science rather than in economics, and the newer chairs emphasize this orientation. Many of the courses

at the school can be offered for degrees in arts or law. Influenced in part, no doubt, by its location in the administrative and financial center of the country, and by the practical interest of many of its faculty in concrete social problems, the school has stood for a realistic and more comprehensive treatment of the social sciences and has revolutionized their status as academic disciplines. Elsewhere the organization of social science teaching generally groups around one central degree: the Economics Tripos or the economics special subject in the B.A. at Cambridge, the Honour School of Philosophy, Politics and Economics at Oxford, the degrees in economics or commerce at the other universities. The Cambridge staff includes thirteen economists and seven other members—economic historians, a statistician and a political scientist—and for intellectual distinction ranks high among the universities of Europe.

Methods of teaching are not uniform. At Oxford and Cambridge attendance at lectures is not compulsory and their subject matter represents a compromise between the personal interests of the lecturers and the syllabus for the examination. The inadequacies of the lectures are supplemented by an elaborate tutorial system which affords the student an opportunity for discussion and for obtaining criticism and advice as to reading. In London and in most of the provincial universities students are required to attend a minimum of lectures, which generally cover in outline the field set out in the syllabus, give guidance in reading and supply contemporary material and criticism. The London School of Economics also offers a large number of lectures on special subjects at which attendance is optional. Students at the school are attached in their first year to an adviser of studies who fulfils some of the functions of the tutor at the older universities; while in their second and third year the work of the students is supervised by the professor in charge of the department in which they have elected to specialize.

The line of division between the discussion class and the lecture is in general quite rigidly drawn, and the main emphasis is laid upon the lectures (which are frequently followed or supplemented by discussion classes). At all universities the writing by undergraduates of essays which involve considerable individual research is an integral part of the educational system, although the standards of performance vary widely. The universities usually aim to avoid the

use of texts; they encourage students to read widely and to coordinate their knowledge in class or in personal conference with the teacher. In the smaller colleges, however, where the staffs are small in relation to the number of students and to the subjects to be taught, the use of texts is more common, although the number of texts of university grade is relatively small.

II. THE DISCIPLINES. In order to discuss the development of the teaching of individual social sciences it is necessary to make an arbitrary definition of the social sciences as a group and of the scope of each subject, although in fact the distinction between the subjects is vague and is becoming more so as lines of approach and emphasis are modified in response to new doctrines in neighboring fields. It is possible, however, to distinguish four main groups: economics (including banking and currency, public finance, commerce and industrial organization, as well as theoretical and applied economics); history as a social study; law; and sociology (including anthropology and political science, the latter embracing the practise and theory of government).

Economics is today the most widely taught of all the social sciences, and since it was the first to enter the academic field it bore the brunt of the resistance to social science teaching. It was taught with varying degrees of effectiveness in the Scottish universities in the eighteenth century as part of the ethics section of moral philosophy, but it was only from Adam Smith that it received comprehensive and systematic treatment. Smith's friend Millar continued the tradition in part and dealt with economic doctrines in his law classes from 1761 to 1801. At the beginning of the nineteenth century Dugald Stewart at Edinburgh and Mylne at Glasgow were delivering separate courses on political economy. By the time of the Scottish universities Commission of 1831 the subject was being studied at all the universities except Aberdeen, for its own sake and not for the light it threw upon man's duty to man. Yet the recommendations of the commission that there should be professorships in political economy at Edinburgh and Glasgow were not carried into effect until 1870 and 1896, although a special lectureship was created in Glasgow in 1892.

Elsewhere in Great Britain, superficially at least, the situation appeared even more promising at the beginning of the nineteenth century.

Beeke and Symonds, the professors of modern history at Oxford and Cambridge, had introduced some discussion of economic doctrines into their lectures before 1810, and Malthus' appointment in 1805 as Professor of General History, Commerce and Finance at Haileybury, the East India Company's college, was followed in 1825 by Senior's appointment to the newly created Drummond Chair of Political Economy at Oxford. Meanwhile at Cambridge Pryme had delivered a course of lectures on economic theory from 1816, and was created an honorary professor in 1828. With the appointment of McCulloch in 1828 to a professorship in political economy at University College, London, of Richard Jones in 1831 at King's College, London, and of Longfield in 1832 to the new Wheateley chair at Dublin, political economy seemed to have gained a secure foothold in the university system. But we have seen that the facts were otherwise. The lectures, usually limited to one course, frequently extended over only a part of the year and were but poorly attended; there was no opportunity for advanced work. Senior himself regarded the Oxford professorship as "rather for the purpose of occasioning books to be written than of affording oral instruction," and the same view seems to have been held by Wheateley, Lloyd, Neate, Merivale, Twiss and other holders of the five-year chair. Although individual tutors occasionally lectured in the field, no second teaching appointment was made at Oxford until the creation in 1907 of an economic history lectureship (later a readership), to which a readership in economics was added in 1925. Both Thorold Rogers and Bonamy Price were active occupants of the Drummond chair, and in the eighties interest in economic subjects at Oxford revived, thanks partly to the personal enthusiasm of Toynbee. The treatment of economics at Oxford has been largely historical, in that emphasis is laid upon the study of past theories in relation to their historical setting, and teaching has been conditioned by the Oxford educational ideal to which reference has been made. Quantitative and statistical treatment of economics is almost entirely lacking and statistical material is but poorly represented in the Oxford libraries.

At Cambridge Pryme's lectures continued with occasional intermissions until 1863, when a paid professorship was created. Fawcett, as the first professor, delivered lectures which were classical in emphasis, and it was not until Marshall's appointment in 1885 that the influ-

ence of the work of European economists made itself felt in the teaching of economics. The change in emphasis was apparent at once; the scope of economics widened and the statistical and historical approaches were emphasized. As at Oxford, however, additions to the staff came but slowly. Lectureships in economics were created in 1896, 1904 and 1911, and in statistics in 1912. Nevertheless the scope of economics as taught at Cambridge is narrower than at London, especially in that less attention is given to the modifying influence of the other social sciences and much more time devoted to pure theory and to logical training. But Cambridge is, despite Edgeworth's long tenure of the Oxford chair, the most important center of mathematical and neoclassical economics in Great Britain.

In London the teaching of economics, which was suspended when McCulloch ceased teaching at University College, was resumed after Waley's appointment in 1853; but despite a succession of professors as able as Cairnes, Courtney, Jevons and Foxwell the subject, for reasons already indicated, failed to attract many students. After Jones' appointment as Malthus' successor at Haileybury in 1835 the teaching of economics ceased at King's College, London, for the professorship of principles and practise of commerce held by Joseph Lowe in 1831 seems to have been legal in emphasis. The Tooke professorship, created in 1859, like the Whateley professorship in Dublin, was remarkable rather for the quality of the men who held it (Thorold Rogers, Cunningham, Urwick, Hewins) than for the number of students attracted to lectures.

As already indicated, the real step forward in London began with the establishment of the London School of Economics in 1895 and the creation of a degree in economics in which economic theory was the central vitalizing principle. As the school has developed and the subject broadened out, professorships and readerships have been created to deal with such specialized topics as banking and currency theory, international trade, commerce and industrial organization; the emphasis, however, is on the essential unity of the study of the economic aspects of society. While under Cannan the approach to the advanced work in pure theory has been historical in emphasis, a course in the history of theory being the core of the work of the second and third years, Cannan's own skeptical common sense and interest in applied economics, together with the breadth of the curriculum and

the emphasis upon the interaction of all the social sciences, which is so marked a feature of the school, have tended to develop a center of economics teaching which is institutional and historical as compared with Cambridge, and statistical and concrete as compared with Oxford.

In other universities developments have been slower. In 1894 when the British Association investigated the teaching of economics, lectureships in economics existed only in Bristol, Manchester, St. Andrews and Glasgow, although there had been professorships in Edinburgh and Liverpool since 1870 and 1891 respectively. At a few other colleges some teaching was given by professors of philosophy or history, but everywhere the treatment was narrow in scope and subordinate to other subjects. There were "little more than general opportunities for showing economic knowledge in examinations primarily devoted to other subjects," and an almost complete absence of advanced study. The growing interest in social problems that marked the turn of the century, together with the increased economic pressure of Germany and the extension of government activity, attracted greater attention to the study of economics. This change was materially assisted by the new and more liberal conception of the subject that was beginning to prevail as a result of the work of Marshall and Cliffe Leslie, and of the economic historians Cunningham and Ashley. Economics departed more markedly from philosophy and logic as the breadth of its scope and the subtlety and complexity of its doctrines came to be appreciated. These forces have led to the creation of departments of economics, commerce or administration, and since the war students have turned to economics in increasing numbers; nevertheless outside the three larger universities the degrees seldom attract as many as thirty students a year and, except at Liverpool, Manchester and Birmingham, the economics faculty in its widest interpretation rarely exceeds six or eight persons and is usually much smaller. The nature of the teaching is conditioned by the fact that the curricula of these colleges are largely based upon those at London, and until recently most of the teachers have been trained at Oxford and Cambridge. The approach to economic theory has therefore been in the main that of Marshall.

Unlike some of the other social sciences, history has been studied at the universities from the time of their foundation. The development

of history teaching, therefore, has been the story of the adoption of a broader view of the scope and content of the subject, and of its enrichment by the opening up of new sources of material during the nineteenth century and by the infiltration of influences from the other social sciences. Despite the existence of professorships in history, historical studies long remained closely connected with the classics. As late as the middle of the eighteenth century attention was focused mainly upon ancient history and textual commentary. Until 1886 history was regarded at Oxford as an easy discipline which had to be stiffened by an admixture of law. History textbooks, according to information furnished to the Commission of 1852, were written mainly by foreigners, frequently untranslated, while their superiority to native literature was declared "incontestable."

Furthermore, when in the latter half of the century history was elevated to the status of an honors subject and additional teachers were appointed, those selected favored a school of history which emphasized constitutional and political developments. This applied especially to Oxford, famous for its history department; there Stubbs, while reviving the study of English history and making available sources hitherto inaccessible, tended to narrow the view of the historian and this attitude received confirmation from his successor, Freeman. The unreliability of Buckle's brilliant work limited his influence in academic circles and, although the scope of history was widened under Kingsley and Seeley at Cambridge, Cunningham complained in 1898 that the study of social history "received little recognition in academic and scientific circles." Toward the end of the century, however, there was a marked increase in the number of teaching appointments, while the personal influence of such historians as Toynbee, Cunningham and Ashley who were keenly interested in economic history, and of such economists as Leslie and Rogers who desired to broaden the basis of economics, operated in favor of a new view of history. Since the beginning of the twentieth century economic and social history has attracted some of the most brilliant workers in the social sciences. At Birmingham under Ashley, at Manchester under Unwin, at Cambridge under Cunningham and Clapham, and at London under Knowles and Tawney, important schools of social history have developed; and courses in economic history are given at all universities. In the schools devoted solely to history, how-

ever, now very important numerically, the new history has developed side by side with the older constitutional or political history, but it enters only as one of several papers in the main history examination and has not as yet led to a new synthesis. The greatest developments of social and economic history have occurred in the schools preparing for degrees in commerce or economics.

Sociology found no place as a special subject of study in any of the universities until 1904, when Spencer's death stimulated the academic recognition of his favorite subject more than had his lifetime of agitation. At Edinburgh Geddes founded in 1892 a school of sociology which was not connected with the university and which sought a biological synthesis of social studies and applied the theories of Comte and Le Play to the study of civic evolution. This movement, largely outside the universities, has led to the foundation of various civic societies, and to the establishment of summer schools where the methods of Geddes have been applied to the study of the regions where the conferences have been held.

The first formal university course in sociology was given at the London School of Economics in 1904; in the same year the subject obtained recognition in the curriculum of the university, and in 1905 a second lectureship was established. In 1908 both lectureships were changed to professorships. Additional members have been appointed to the staff since 1918, especially in the allied fields of anthropology and ethnology and lectures have frequently been delivered by non-academic experts. Yet despite the offer of scholarships to promote its study the subject failed to attract many students, although the addition of the London School of Sociology in 1912, under the title of the Ratan Tata Department, stimulated the study of elementary sociology and led to further additions to the staff. Under Hobhouse at London the teaching of sociology has reflected his views as to its scope and content. Sociology has been the study of social institutions and behavior; sociologists have sought, on the one hand, a unifying principle coordinating the social sciences and, on the other, an evaluation of social development with a strong emphasis on social philosophy. This sociological approach has considerably influenced, and has been itself influenced by, the study of the closely allied subjects, political science and anthropology. Apart from the schools of social work already referred to, sociology outside of London can be studied as a

special discipline only at Liverpool, where a department of social science with three lecturers and a professor has existed since 1923. Independent lectureships in sociology have existed for short periods at St. Andrews and Aberdeen.

The Scottish professors lectured on aspects of political science in connection with the moral philosophy courses before 1800, and the study occasionally found its way into the classical studies at Oxford and Cambridge before 1850. Thereafter it secured a recognized, though minor, place in the various honors schools; but although occasional lectures were given by interested Fellows, the study was not seriously pursued, and to this day the absence of standard and comprehensive works has hindered its development. At Oxford where a readership created in 1910 was made a professorship in 1912, and at Cambridge where a professorship was created in 1927, attention has centered in political theories and their development. Political science has been studied at the London School since the second year of its existence. A professorship in public administration was created in 1913 and in political science in 1915. There is today a considerable staff, and many students offer public administration as their main subject for the honors degree. The teaching covers both the development of political ideas and a study of the practical operation of political and administrative institutions. In these later aspects the study has been influenced by the work of the Webbs, and by the psychological approach of Wallas, whose *Human Nature in Politics* and *The Great Society* suggested new and fruitful methods of attack. Elsewhere the subject, if treated at all, is taught by a special lecturer or by the professor of philosophy.

Psychology, although established in the academic field by the beginning of the twentieth century, has claimed affinity with the natural rather than with the social sciences. Through the work of McDougall, Ginsberg and, for a tragically brief time, Rivers, it has considerably influenced the social sciences, although the implications of the newer psychology have had less influence on economics in England than in other countries. The recently established department of industrial psychology at Manchester, however, promises important developments.

In the latter half of the eighteenth century Millar of Glasgow had lectured and written on anthropological subjects, and at Edinburgh the professor of civil law had touched upon the field in the early years of the nineteenth century.

Nevertheless the efforts of the Royal Anthropological Institute and its two parent societies failed to obtain explicit academic recognition for anthropology until 1884, when Tylor was appointed reader at Oxford. Interest in this subject was first aroused in the universities by the professors of anatomy and of archaeology. Among the former Rolleston of Oxford prepared the way for Tylor, and McClelland at Cambridge delivered lectures in physical anthropology in 1884. Among the archaeologists Ridgeway in particular enriched the study of archaeology from 1882 by introducing anthropological methods and concepts, and by focusing interest in the subject by the formation of the University Anthropology Club in 1896. A lectureship in physical anthropology was created at Cambridge in 1893, and additions to the staff have since been made at both universities. Central boards of studies were created in 1904 to coordinate the work of the specialists whose lectures impinged on anthropological fields. An Anthropology Tripos was established at Cambridge in 1913, but has seldom attracted more than one or two students. Great stress is laid at Cambridge on field work of graduate status. At Oxford, except for an occasional student who may offer it as an additional subject in the Honours School of Natural Science, the study of anthropology is confined to graduates who may offer the subject for the B. LITT., B. SC. or PH. D. degrees. Efforts are made, however, to offer courses covering all aspects of the subject. In London anthropology has been taught in connection with sociology since 1904, and is now well recognized in the examination syllabi. It has gained considerably in popularity since 1918, and the teaching staff has been strengthened by the addition of workers in social anthropology. The main centers are University College (for physical and cultural anthropology and archaeology) and the London School of Economics (for ethnology and cultural anthropology), while physical anthropology is studied at King's College. Courses in ethnological subjects are delivered at the Imperial Institute and at the School of Oriental Studies. More coordination among the teaching groups is needed, and the subject, especially in the undergraduate courses, so far has failed to attract many students.

The British Association endeavored in 1900, and again in 1913 and 1923, to promote the academic study of anthropology. Yet except in the three larger universities, and at Liverpool, where courses have been developed in connec-

tion with the University Institute of Archaeology, and at the University of Wales, where anthropology is an important part of the honors course in geography, anthropology scarcely enters the teaching field. The teaching of geography is, however, being broadened to include some study of ethnology, and lectures in physical anthropology are given by the professors of anatomy in at least four colleges, although as a rule they are not compulsory. There is no doubt, however, that methods and results of anthropological studies are beginning to influence the teaching of other social sciences, especially sociology and economics.

It has already been suggested that law has in the main failed to receive attention as a social science in Great Britain because of the attitude of its professional organization and the educational theories held by the older universities. Chairs in civil law were established at Oxford and Cambridge in 1546 and 1540, and in English Law in 1758 and 1800. Nevertheless the Royal Commission of 1852 was informed that the Oxford professorship of English law was "a sinecure and a sham," and that the Regius professor of civil law had not lectured for more than a century. At Cambridge the situation was little better, and law was studied largely as an alternative to other subjects considered to be more difficult. The most comprehensive teaching was in Scotland, especially at Edinburgh and for a time at Glasgow, but the Commission of 1831 regretted the fact that law was not studied "as a liberal and enlightened subject." In the middle of the century Trinity College, Dublin, was an outstanding exception to the general decadence of law teaching. A series of investigations in England, a House of Commons inquiry in 1846, inquiries by the London University Commissions of 1895 and 1913, and deputations and discussions by the National Association for the Promotion of Social Science, all failed to stimulate the teaching of law in its wider aspects. Proposals for the establishment of a great law college in London, made intermittently since the middle of the nineteenth century, have all proved abortive because of the opposition of interested parties. Meanwhile the law staffs have been increased at the universities, especially in the fields of jurisprudence (beginning with Austin's appointment to the chair at University College, London, in 1828), Indian law, international law and commercial law, the initiative in all cases coming from the London colleges. The newly formed universities began to develop

law departments at the end of the nineteenth century. The movement was accelerated by the passage of the Solicitors Act of 1922, but for financial reasons the schools have been mainly professional.

The legal teaching controlled by the professional organizations is in the hands of lecturers the majority of whom are barristers, although some are members of university staffs. But the study of law as a subject for honors or for advanced degrees is growing in favor in the three larger universities. Undergraduate teaching is dominated by the desire to make the degree the vehicle for a liberal education. The fourth year (for a higher degree) aims definitely to provide professional training. Teaching methods have not changed noticeably. Occasional use is made of the case method in a modified form, but with no consciousness of any epoch making departure from traditional teaching technique.

The study of law has, however, been much enriched by the influence of Maine, Maitland and Vinogradoff. If Maine broadened the basis of the study of law by linking it with an analysis of historical developments, Maitland revealed the potentialities of legal sources for advanced historical studies. Vinogradoff not only developed both fields but also united them with the broader study of social development. Unfortunately the preoccupation of the older universities with undergraduate teaching prevented any of the three men from developing great new schools of legal research. They have introduced a study of historical development into the teaching of law, but the philosophical and sociological aspects of the subject remain relatively neglected. Some progress may be expected in the future from London, where the three large colleges have taken steps to coordinate their teaching, while the London School of Economics is showing a distinct tendency to direct attention to the importance of the study of law as an integral part of the study of society.

III. THE PRE-UNIVERSITY SCHOOLS.

The introduction of the social sciences into the pre-university educational system has been extremely tardy, owing partly to the slow progress of public education and partly to the sharp line drawn in the nineteenth century between primary and all other education. Since the primary schools were intended to meet the needs of a class which would obtain no other education and which would attend for but a short period, attention was concentrated upon imparting the

rudiments of reading, writing, grammar and arithmetic, with possibly a very little history. The teaching at the non-primary schools was dominated by the requirements of universities which, as we have seen, emphasized classical or mathematical studies.

From 1840 onward William Ellis began teaching social economy in the primary schools of London, and even founded schools on condition that the subject be taught. He also wrote several popular texts. In 1871, when a deputation from the National Association for the Promotion of Social Sciences urged upon the Educational Committee of the Privy Council the teaching of economics in schools under public inspection, it pointed to the work of Ellis and his followers in various parts of the country as evidence that it was possible to teach the subject to young people with success. The committee, however, although willing to recognize the subject when taught competently, preferred that the initiative in its introduction should come from the schools or from the enthusiasm of individual inspectors. Jevons took advantage of this opportunity to secure the introduction of the teaching of political economy into some of the schools in the Manchester district. Although some impetus was given to its study in grammar, high, and secondary schools by the inclusion of political economy as an optional subject in the Oxford and Cambridge local examinations, by 1900 the subject had made little progress in these schools and none at all in the elementary schools.

Political economy is taught today, if at all, mainly in connection with history, itself a somewhat neglected subject. The character of the teaching of history in the schools during most of the nineteenth century called forth the gibe that it "combined the respective disadvantages of the multiplication table and the Newgate Calendar," and not until after Green's *Short History of England* in 1874 had indicated a method, and Traill's editorship of *Social England* between 1893 and 1897 had supplied material, was new emphasis introduced. Recent years have witnessed a movement to teach more social and contemporary history, but the new textbooks have not yet conquered the field. Recently the teaching of geography has been broadened to allow emphasis upon human and historical geography, a change in which the influence of the ethnologist and sociologist is evident. A new impetus to the study of political economy and economic history may be

expected from the recent inclusion of economics as an alternative to science or Latin in the senior schools and the London matriculation examination for which pupils are prepared all over the country.

To encourage the teaching of civics has been the object of the Civic and Moral Education League (formed in 1898 as the Moral Education League) and, from 1920 onward, of a special committee of the British Association. In the public elementary schools some indirect attention is paid to what might be regarded as civics in connection with lessons in history and in health, and some specific training in civics is given in individual secondary schools. Opinions as to its utility, however, differ widely. The number of textbooks on civics is large, but the problem of devising a course which shall avoid both details of government administration and civic duties, and moral maxims and patriotic exhortations, is not yet solved.

IV. POPULAR INTEREST. Popular interest in the social sciences has fluctuated in both intensity and direction. At the beginning of the nineteenth century economics was a popular fad. This situation was due in part to the industrial changes of the time and to the war, both of which were raising acute economic problems, and in part to the publication, following upon Smith's *Wealth of Nations*, of a series of books which for the first time gave promise of a science of economics. The sequel is evident in the enormous popularity of such expositions as Mrs. Marcet's *Conversations* and Harriet Martineau's *Tales in Political Economy*, and in more educated circles in the space devoted to social and economic discussions in such journals as the *Edinburgh* and *Quarterly* reviews. In the middle of the century contemporary interest concentrated upon the origin of man and resulted in a great increase in the popularity of ethnology and anthropology. With the publication of Darwin's *Origin of Species* in 1859 public interest reached its peak and thereafter declined. In the last quarter of the century public interest in the social sciences was at a low ebb. But Spencer's work achieved considerable popularity from time to time, and there was sufficient interest in a vague and semi-philanthropical social science to attract the exploitative activities of founders of popular sociological journals which seldom had a long career. Ruskin's lectures and addresses confirmed the prevailing conception of economics as harsh and unrealistic without offering

any positive substitute. The twentieth century brought a marked change. The problem of poverty became of pressing importance, and the development of a political labor party revived interest in the social sciences to such a degree that they are today probably more popular than any other branch of study.

Newspapers and popular periodicals of every creed and party have always been used to influence public opinion on the issues of the day. However, the smallness of the book reading public and the high cost of printed matter of necessity directed the efforts of the promoters of the popular study of the social sciences toward securing a forum from which lectures could be delivered. This need was partly met by a spontaneous movement from the public. Mechanics institutes were established after 1823, and numerous literary and philosophical societies supported by a somewhat higher social class sprang up all over the country, particularly in the middle third of the century. From 1853 the cooperative societies devoted a portion of their funds to education. From 1873 the universities began to offer extension lectures, and the Workers' Education Association, founded in 1903, also provided centers at which lectures could be given and discussions initiated. Despite the closeness of the relation between cooperative theory and economics, the regular classes in the social sciences, organized by the cooperatives from 1897 onwards, have been relatively unpopular, although there is a growing interest in industrial history. Until 1900 very few lectures on social science topics were given under the auspices of the university extension movement, but in recent years their number has increased relatively to all other subjects. The first classes in economics given by the Workers' Education Association in 1908 attracted students fewer in number than those attending other subjects, but whose desire to pursue the study more intensively led to the ultimate development of the tutorial class system. Such classes in the social sciences, frequently extending over three years, form over fifty percent of all courses organized by the Workers' Education Association. The proportion is considerably greater in the courses under the auspices of the less important, class conscious National Council of Labour Colleges which broke away from the Workers' Education Association in 1909.

Popular interest in the study of the social sciences has often been stimulated by political or partisan bodies. Of these the most important

have been the Anti-Corn Law League, the Cobden Club and the Fabian Society. The former provided lecturers during the forties to teach political economy (with of course a free trade bias) to vast audiences all over the country. In 1843 alone the league distributed a million tracts through a staff of eight hundred persons. In 1866 the Cobden Club, animated by a similar interest in free trade, organized lectures, arranged for the publication in cheap form of economic works which advocated their principles, and from 1874 onward offered prizes for essays on economic subjects to students attending the universities and university extension courses. These prizes are still offered, although the other activities of the club have become unimportant. From 1884 the Fabian Society has diffused an interest in the study of the social sciences reaching far beyond its own membership through the publication of cheap *Fabian Tracts*, by holding public meetings and by providing lectures. More recently social questions have been studied by conferences and summer schools under the auspices of the different political parties.

The social sciences have been peculiarly fortunate in attracting the interest of men with an almost fanatical belief in the importance of promoting the study of their favorite science: McCulloch, who delivered lectures in Edinburgh and London and was an active publicist; Lord Brougham, who formed societies and financed the delivery of lectures and the publication of literature; Ellis, who founded schools and delivered lectures in various parts of the country; Hunt, the energetic founder of the Anthropology Society who delivered lectures everywhere and published magazines at his own expense; Spencer, the latter part of whose life was a constant plea for the study of sociology. The learned societies, too, have played their part, especially anthropological, ethnological and sociological societies. One of the most important achievements of the National Association for the Promotion of Social Science was its success in popularizing and extending the interest in the social sciences, especially in the localities in which its annual conferences were held. Universities and special benefactions have provided from time to time for such permanent lecture foundations as the Barrington, Gifford, Stevenson, Newmarch, or special public lectures which deal with the social sciences. Still more recently lectures in these subjects, delivered by well known experts, have been among the more pop-

ular of the educational courses included in the programs broadcast by radio.

V. THE LEARNED SOCIETIES. In the absence of any lead from the universities the learned societies played a unique part in promoting the study of the social sciences in the nineteenth century. For the greater part of the period they provided the only center where specialists could meet, and not only supplied a platform for the reading and discussion of papers and usually a medium of publication, but also pressed the claims of their sciences on all occasions, and agitated to secure for them greater academic recognition. Most of the teachers of the social sciences were members of one or more of these societies, and new teaching appointments were frequently made from among the more prominent members.

Of the large number of relatively small discussion groups and clubs (such as the Trijackea, the Utilitarian Society and the Edinburgh Speculative Society) which flourished in the first quarter of the nineteenth century and which were attended mainly by the Benthamite radicals or the so-called classical economists, only the Political Economy Club survives. This famous society was founded in 1821 by Tooke with the object of "promoting the knowledge of political economy"; members were to regard "their own mutual instruction and the diffusion among others of just principles of political economy as a real and important obligation." Its small and limited membership, which originally included Ricardo, Malthus, Senior, McCulloch and Whately, consisted mainly of business men, politicians and public officials, but certain professors were later made members *ex officio*. Although in the century of its existence its members have included most of the chancellors of the exchequer and many well known public characters and prominent economists, the club has been famous rather than important. The quality of its debates has not always been maintained, and its limited membership and the absence of organized publicity have prevented it from playing a large part in the promotion of the study of economics outside its own ranks.

The discussions at the club, however, provide in miniature a history of the development of economics during the century. Holding a firm belief in the existence of "sound political economy" the club at first confined itself to the settlement of debated points of theory and the search for agreed and final definitions, and often

disposed of as many as three issues in one evening. In the third quarter of the century the club became more interested in concrete problems; although doubts as to the invincible wisdom of laissez-faire began to obtrude themselves, it was still assumed that "whatever is in accord with the laws of political economy is necessarily right and proper and vice versa." In later years elaborate papers occupying the whole evening have come to take the place of the less formal discussions between members, so that "the provinces of the Statistical Society and the Political Economy Club tend to become confused."

Three statistical societies exist in Great Britain. The oldest, the Statistical Society of Manchester, was formed in 1833 and at first worked through committees which collected material and rendered reports on social conditions. These were at first published separately, but since 1853 have been included in a *Journal*. The majority of papers have been statistical or theoretical treatments of particular economic or social problems. Very few papers have been devoted to statistical technique, and in this respect the character of the society is unchanged today and closely resembles that of the more important Statistical Society of London. This latter society, which was formed in 1834 with a membership that included Malthus, Babbage, Richard Jones, Tooke, Senior and Whewell, was originally divided into four great sections: political, economical, medical, and moral and intellectual. The *Journal*, which continues at the present time, was first published in 1838. Fear of political entanglements led the society until 1857 to exclude discussion of causes and effects from its field and to concentrate on the collection of facts. Of recent years more attention has been paid to methods and technique, with which about a third of the printed papers are now concerned, but a detailed report on some statistical investigation more frequently affords the basis of discussion at general meetings. Committees of the society have been appointed from time to time to deal with specific problems such as the taking of the census, or to report on housing, strikes or education. In 1927 a proposal was made for less formal meetings at which junior members of the society could discuss developments of interest to the science as a whole.

A more general interest in social questions has characterized the Statistical Society of Dublin, formed in 1847 through the efforts of Hancock, at that time Whately professor. Its object

was to "promote the study of statistical and economical knowledge," and the papers read at its meetings were printed at first separately but from 1855 onward in the society's *Journal*. A Social Inquiry Society was formed under its auspices in 1850. In 1862 the parent society was itself reorganized on the lines of the National Association for the Promotion of Social Science which had visited Dublin in the previous year, and its name was changed to the Statistical and Social Inquiry Society of Ireland. Prizes were offered for investigations into special subjects, and in 1875 a special Charity Organization Committee issued a series of important reports. In addition to the activities of its subcommittees and its efforts to build up a library, the society holds monthly meetings at which papers are read. In 1851 a branch society was formed in Belfast.

In 1832 the British Association created with some misgivings a section for statistics, with interests in early years closely resembling those of the Statistical Society. Gradually, however, papers on economic and social topics predominated, and in 1864 the section became Section F (Economic Science and Statistics). Papers have since been of two kinds: reports on the social and economic conditions of the district in which the meeting for the year was held, and papers, mainly descriptive, dealing with special topics of contemporary interest in the field of economics. Singularly little attention has been paid to problems of method and technique, and although occasional presidential addresses have endeavored to give a synthetic view of the state of the science or to suggest outstanding problems, little has been done to give unity to the discussions at different meetings. Papers continue to reflect the particular bent of individuals.

The Royal Economic Society, founded in 1890, has a large membership but is mainly a publishing society, and very few meetings have ever been held. Its *Economic Journal*, published quarterly, is, however, the most important economic publication in Great Britain, and more recently it has subsidized the publication of books. The Christian Social Union, which existed from 1890 to 1914, published leaflets and arranged lectures. Its journal, the *Economic Review*, was not only the first economic quarterly but also maintained a high scholastic standard and represented all shades of opinion. The study of economics has been promoted by other societies such as the London Economic

Club, small private societies at Oxford and Cambridge, and the Scottish Society of Economists (formed in 1897). The Association of Teachers of Economics, formed in 1924, has tended to give prominence to papers on special topics in which readers have carried out research, at the expense of discussions on teaching and the problems of the science as a whole.

Anthropologists have always been active in their learned societies. The Anthropology Section (H) of the British Association, created in 1884 as the result of long agitation by anthropologists, has been one of the most active units of the association and has, unlike the Economics Section, made extensive use of the committee system provided by the association for the purpose of dealing with matters of interest to the science as a whole. The Ethnological Society, formed in 1844, had a checkered career, but did valuable work in bringing together the few individuals who were interested in the subject. Its timidity in entering controversial fields and its deductive methodology led James Hunt, an ardent but not always wise anthropologist, to break away and form a rival Anthropological Society, which did much to broaden the study of the science in Great Britain by the translation and publication of works by foreign anthropologists. Until 1871 when, after the death of Hunt, Huxley was instrumental in achieving the amalgamation of the two societies to form the Anthropological Institute, anthropological study was hindered by disputes between the two groups concerning the origin of man, which came to a crisis over the Governor Eyre prosecution. Since 1871 a more sober and scientific atmosphere has prevailed.

All three groups had published journals which provided for the publication of research and the diffusion of a knowledge of the work done at home and abroad. The *Journal* of the institute is its main organ, and *Man*, a publication dealing with current literature and containing short contributions from field workers, has been published since 1901. For many years the scope of the science troubled the institute, and successive presidential addresses offered definitions of the field and rejected those of their predecessors. Of the large number of papers read and published during the last fifty years, those on physical or anatomical anthropology and on archaeology have gradually ceded place in numbers to papers on cultural and social anthropology. Contributions of varying quality are made also by the Folk Lore Society (founded in 1874),

the Royal Archaeological Institute of Great Britain, the Society of Antiquaries in London and numerous local archaeological societies.

The National Association for the Promotion of Social Science, founded in 1857, emphasized for nearly thirty years, in its annual congresses and weekly meetings and subcommittees, the importance of a study of the social sciences. Among its large and active membership were numbered many of the leading jurists—including Westlake, Harcourt and Levi—and most of the academic economists of the period. J. S. Mill, Fawcett, Jevons, Newmarch, Farr and Chadwick were among the members of the executive committee, which also included some seventy to eighty members of Parliament, a fact which enabled the association to give legislative effect to many of its proposals. The association published an annual volume of *Transactions* and occasional special reports. The object of the association was to afford those engaged in the numerous reform activities of the time "an opportunity for considering social economics as a great whole." Brougham and his optimistic cofounders believed that the association would be the means of discovering the "moral laws of the universe," which were "no less uniform, less simple and less secure" than the physical laws studied by the British Association. And yet despite its emphatic "belief in the unity of the social sciences" the greatest work of the association was accomplished precisely when it departed from its original aims. From the first the scope of the field to be covered led to a division into five sections, ultimately reduced to four: jurisprudence and amendment of the law, education, health, and economy and trade. The division was inevitable if advanced work was to be done, but certain to obstruct the desired synthesis of the social sciences. The addresses of the presidents of the sections at the annual congresses furnished no great measure of coordination, and in fact the sections went their individual ways. Especially noteworthy was the work of the section on jurisprudence, which amalgamated in 1863 with the Law Amendment Society, itself founded in 1844. It was directly responsible for many of the numerous coordinating and simplifying legal measures enacted between 1860 and 1885. Above all it stimulated many discussions by active lawyers as to the purpose of law and the relation of content to form, and led to a renewed interest in jurisprudence and, by virtue of Westlake's activity, in international law.

The scholastic achievements of the other sections were less significant. If those dealing with education and public health on the whole avoided deep speculative waters, it was because they found much practical work at hand; but even so the papers at the sessions contain valuable material on the social condition of Great Britain at the time. The economics section, producing less spectacular concrete results, was responsible for a series of valuable papers and reports on economic conditions, whose descriptive nature and reformist bias supplied a much needed balance, and allayed the prevailing suspicions in regard to the compatibility of economic theory and practical reform.

More lasting stimulus to the study of sociology, however, came from the Sociological Society, formed in 1903 in order to bring together the students of the individual social sciences "to set forth the unity of the social world and to organize more effective cooperation." A minority of the members were specialists engaged in research, but the majority were persons with general interests, or practical workers who encountered sociological problems in their daily work. The society published three volumes of *Papers*, replaced in 1908 by the quarterly *Sociological Review*, in which papers read at the meetings were discussed. From time to time groups of members formed special committees to consider particular problems. The earlier discussions centering around the objects and scope of the science attracted attention both abroad and at home, and did much to remove popular misconceptions as to the meaning of sociology. Later, as a diversity of subjects appeared in the discussions, the society operated rather to broaden the views of specialists in their own fields than to develop a new synthetic science. A cleavage between the views of the groups led respectively by Geddes and Hobhouse left the former group predominant in the society, and since about 1914 the *Review* has mainly reflected its interests. The influence of this group was further strengthened by the foundation by two of its members of the Le Play House Trust in 1920, which facilitated the correlation of work in the field of civic surveys and also made possible the collection of materials and exhibits.

Shortly after the war the Sociology Club, under the leadership of Hobhouse, was formed at the London School of Economics with the object of coordinating the work of students in the fields of the social sciences. The club meets

two or three times a term but publishes no records of its proceedings.

Until 1886 all efforts to found a historical review met with rebuffs from publishers. The Royal Historical Society, which in 1868 was formed to promote the study of history, was for long composed mainly of amateurs. From 1886, however, the quarterly *English Historical Review* has been issued, which publishes researches on specialized topics in the field of political and administrative history. The Historical Association, founded in 1906, is more popular in appeal, and has a large membership with numerous local branches. Interested mainly in the study and teaching of history, it maintains a library, has annual meetings at which papers are read, publishes bibliographies and, since 1916, a quarterly, *History*. The society has done much to broaden the teaching of history.

In 1927 the Economic History Society was formed to promote the study and teaching of economic history. Its membership consists largely of teachers of the subject, whose interests it aims to promote. It publishes an annual volume embodying the results of research by individual members. Other historical publications which deal from time to time with history as a social science are the *Scottish Historical Review* and the newly formed *Cambridge Historical Journal*. Since 1926 the Royal Economic Society has published an additional annual volume devoted to contributions to economic history.

Mention has already been made of the activities of the Incorporated Law Society and the Council of Legal Education. Several other societies exist or have existed to promote the study of law. The Legal Education Association was formed in 1870 to improve the study of law and to secure the creation of a law university in London. Failing in this latter aim, the society handed over its funds to the Law Society in 1901 after having accomplished useful work in directing attention to the importance of reform in legal education. In 1889 the Scottish Juridical Society, formed several years earlier, commenced the publication of the *Juridical Review*, which has consistently emphasized the closeness of the connection between political science and jurisprudence. The Society of Comparative Legislation, formed in 1894 to apply the comparative method to jurisprudence, has published from 1896 onwards the important *Journal of Comparative Legislation and International Law*. The Society of Public Teachers of Law, formed in 1908, is of more interest to

the student of social science teaching. It has done excellent work in improving the quality of teaching and in broadening the syllabi. Papers are read at annual meetings and since 1924 a *Journal* has been published. Occasionally committees are formed to investigate special subjects. The Society of Commercial and Industrial Law, formed in 1921 by teachers in these fields, is of minor importance. The most important English law journal is the *Law Quarterly Review*, first published in 1885 under the editorship of Pollock. It contains technical legal articles, notes on current cases and book reviews.

VI. RESEARCH. Special training for research in the social sciences has developed but slowly in Great Britain, even since the war. Not only has research generally been regarded as the pastime of the enthusiastic individual, but it has been assumed that a thorough undergraduate training without further supplementation qualified a man for research. The universities have been slow to admit the necessity for a training too technical for inclusion in undergraduate courses. Even in the London School of Economics which, founded as it was under the influence of Sidney and Beatrice Webb, in its early program emphasized the importance of research technique, the teaching work is still organized primarily to meet the needs of undergraduates. As in other universities, the professors have a relatively large number of undergraduate courses and the methods of research training have not been clearly worked out. The school differs from most of the other universities in the large number of specialists in the social sciences on its staff, and in the attention paid to research seminars in individual subjects. Elsewhere, with such outstanding exceptions as the work of Tout in the Manchester History School and of Vinogradoff in jurisprudence at Oxford, the seminar has been little used as a method of graduate training.

Some research training within the universities is provided by the Galton Laboratory for National Eugenics, which publishes the *Annals of Eugenics*, and by the Biometric Laboratory, which publishes *Biometrika*, both at University College, London. In another field the Institute of Historical Research is an important center for study and training, although it has little concern with the broader aspects of history.

Quite as apparent as the lack of specific training for research has been the need for coordination of whatever research is carried on. The

learned societies might have promoted the discussion of common problems among experts, but they have not been greatly concerned with methods or techniques. The overlapping and confusion have been somewhat diminished, however, by the concentration of work in the social sciences at the London School of Economics, which has attracted more than seventy percent of all research students. In 1928 a Social Science Research Training Committee was set up in London to encourage the scientific development of economics and sociology, and "to secure the advantages of interchangeability and comparability in the results of research work" at the different universities. It is significant of a new emphasis that the committee in awarding scholarships for research will pay more attention to the methodological potentialities of the problem chosen for investigation than to any intrinsic importance in the subject itself.

Although inducements for research in the social sciences have increased since 1918, particularly in the generous traveling research fellowship and in the direct grants to British universities by the Laura Spelman Rockefeller Foundation, the relative financial poverty of the social sciences still affects seriously the volume and nature of advanced research. It has been reflected in the slight development of institutes for corporate research. Occasionally universities have organized cooperative programs, and groups of individuals have undertaken such work as the Cambridge histories. The more active of the learned societies have from time to time appointed committees for research in particular problems, but large endowed research institutes do not exist.

There are, however, some beginnings of corporate research. In 1923 a Railway Bureau was established at the London School of Economics to conduct research into railway problems. The London and Cambridge Economic Service, instituted in 1923 and supported by contributing firms, although it has only one full time editor and relies upon the teaching staff of the universities for material, issues monthly and quarterly publications and occasional memoranda on special economic subjects. The important Institute of Agricultural Economics at Oxford conducts research and publishes memoranda. The National Institute of Industrial Psychology, which is partially self-supporting, was incorporated in 1921. With a staff of psychologists, psychiatrists, economists and medical men

it undertakes scientific investigation into industrial fatigue, vocational guidance and industrial planning and organization so far as they affect the worker. Occasionally it cooperates with the Industrial Fatigue Research Board and other government departments. Recently various government departments, particularly the Ministries of Agriculture and Labour, have begun to establish research divisions. Some measure of corporate research is also to be expected in the future from the Royal Institute of International Affairs and from the rapidly expanding department of international affairs at the London School of Economics.

Research in the social sciences is still limited by the paucity of equipment, a further reflection of financial poverty. Mechanical statistical devices are few in number and frequently primitive in kind. While the older universities, the British Museum, the Record Office and the law societies possess rich historical and legal libraries, there is a general lack of contemporary and statistical material and of foreign works. More recently the excessively high prices charged for official publications have further limited the purchase by university libraries of essential source material. The learned societies have made the collection of a library one of their main objectives, and the Statistical Society has frequently suggested improvements in the collection and presentation of statistics by the government. At present important collections of physical anthropological material exist at many of the universities, but the famous Pitt Rivers Collection at Oxford was originally a private collection, and for many years the Anthropological Institute stressed with little success the importance of adequate museums. Until the foundation of the British Library of Political and Economic Science at the London School in 1895 there was no complete collection of literature relating to the administrative authorities of the country. But since the eighties of the last century the British Museum collections have been enlarged and rendered more accessible; and the availability of the rich resources of the many private and public libraries of London will be greatly increased after the publication of the comprehensive London *Bibliography of the Social Sciences*.

VII. CONCLUSION. There is ample evidence that the long fight of the social sciences for academic recognition is to have a triumphant conclusion. The prejudice against them is dis-

appearing, while the events of the post-war years have directed attention to the pressing importance of social problems of all kinds. That this increased interest in the social sciences is not confined merely to those of practical importance, such as economics, is indicated by the recent foundation of the important British Institute of Philosophical Studies.

Since the war there have been at all the universities marked increases in the social science teaching staffs and in the numbers of students; subjects are being given more prominence in the curricula for first degrees. The success of the London School of Economics will do much to stimulate the popularity of the social sciences as an academic discipline by providing a richly endowed center where all aspects of the field can be studied. The great increase in the numbers of students taking training in research or offering the social sciences for higher degrees is a reflection of the slowly growing awareness of the importance of research technique. Work in the social sciences is coming to be less and less the hobby of the interested amateur. With this changed attitude there is likely to be a change in the relative importance of the learned societies which were of such significance in the

nineteenth century. Now that the universities provide centers where interested individuals may meet those working in similar fields, one of the older functions of the societies has disappeared. They are likely in the future to concern themselves more positively with the organization and coordination of research on a larger scale. And although the question of finance is still crucial, there is likely to be a further development of corporate research, organized either by the universities or the societies or by newly created coordinating bodies.

(London 1852-53). Little has been written specifically on the teaching of the social sciences in Great Britain. However, the reader may consult: British Association for the Advancement of Science, *Report of Meetings*, vol. lxiv (1894) 365-91, vol. lxxxiv (1914) 235-36 and vol. xci (1923) 417-21 (reports on the teaching of economics and anthropology); Society of Public Teachers of Law, *Journal*, vol. i- (1924-); *History*, vol. i- (1912-); and proceedings of the various learned societies as well as the lives of some of the more important teachers of the social sciences.

II

France, Belgium and Romanic Switzerland

I. A history of the social sciences in France would be incomplete if it neglected the whole period preceding the nineteenth century. One need not go back to the Middle Ages, in which one could nevertheless, without forcing the terms, consider as "social sciences" the teaching of the Glossators and especially of the post-Glossators (Bartolus and his disciples) and of the founders of the canon law. The century of the Renaissance and the Reformation without doubt witnessed the flowering of works that brought social problems down from heaven to earth and formulated them in positive terms. It is chiefly in the matter of public and of international law that this change in orientation is significant. To grasp it, all that is necessary is to recall, in connection with the first of these disciplines, the name of Bodin, and, in connection with the second, that of Grotius, whose influence was considerable in France, as in all of occidental Europe. But economic phenomena themselves profited by this great intellectual ferment, and it is not without reason that, before Adam Smith, Montchrétien could be called the father of political economy.

If any generalization is suggested by the examination of the social sciences in their historic evolution, it is surely that they cannot live and flourish except in a relatively liberal medium. All progress in social science (private law, perhaps, excepted) exacts as a necessary preliminary the right to criticize existing institutions, and that right is the very thing which authoritarian and absolutistic regimes generally deny. It is not surprising that the seventeenth century saw scarcely any development of the social sciences in France, either in teaching or in theoretical writing.

The great movement of intellectual and social reform which characterized the following century concentrated on two points—the struggle against the church and the recasting of institutions in the direction of democracy. This is not the place to describe the part played by each of its promoters—Montesquieu, Voltaire, Rousseau, Turgot, Condorcet, Diderot, d'Alembert and the *encyclopédistes*—but it should be

noted that their influence, however powerful it may have been, was indirect. Their invaluable service lies in having drawn public attention to questions of a political and economic order, in having emphasized their importance, in having considered them as possible objects of a positive science. On the other hand the new regime instituted in the wake of the revolution gave prominence to these questions in its program of instruction. Indeed the instruction reserved for the social sciences during the post-revolutionary period was more practical than scientific, in the sense that it had the training of future administrators in view and was largely inspired by the example of Germany, where the study of the so-called "cameral" sciences was customary. It is none the less true that a new taste for the social sciences was asserting itself in France as elsewhere. In support of this statement need only be mentioned two important creations on the part of the Convention, that of a second class of the so-called moral and political sciences at the Institut de France, reorganized in the year IV, and that of the Conservatoire National des Arts et Métiers, which was founded in 1792.

Napoleon's absolute power hardly conformed with liberal reflection on social matters; by a gesture symptomatic of his dislike of ideologists he suppressed the second class of the institute. As for the law courses in the imperial university, they had no other object than the exegesis of the five great codes elaborated in the first year of the century.

The Restoration was no more favorable to social science than the preceding regime had been. But the impulse had been given, and reflection on social facts became more intense each day. Henri de Saint-Simon laid down some of the fundamental principles of sociology and Auguste Comte applied to them the resources of an exceptionally vigorous and original mind. At the same time Fourier began to propagate his ideas, some nebulous, others fruitful. But this whole movement of ideas took place outside the university and, in large measure, as a reaction against it.

The July Revolution was destined to open wider the door to these new trends. Beginning with 1830, a chair of political economy was founded at the Collège de France and entrusted to J. B. Say. Another was created for Garnier in 1846 at the Ecole Nationale des Ponts et Chaussées. At the Collège de France, before an eager audience, Michelet and Quinet treated the most important social problems of the day. Augustin Thierry's works pointed out the influence of collective forces as well as that of individuals. At the newly founded Ecole des Chartes teachers of impeccable erudition, like Benjamin Guérard, tried to give a more veracious picture of the Middle Ages than was given by romantic writers of the same period. Two ministers of the bourgeois monarchy, Guizot and Salvandy, possessed the merit of wanting to give to the social sciences their due place. Guizot, himself a profound and original historian preoccupied with sociology, as witness his *Leçons sur l'histoire de la civilisation*, performed a decisive act in calling Rossi to the faculty of law in Paris to teach constitutional law in a new and really scientific spirit. Salvandy proposed to give the law faculties a new impulse and to draw up for them a very strict and modern program, which circumstances alone prevented him from realizing.

The protection accorded the social sciences by Louis Philippe was not unlimited, and theories that were too bold were more than once refused the right of expression. Michelet's and Quinet's courses were suspended; Saint-Simonism was alternately popular and discredited; and Proudhon had to struggle all his life against a public opinion which was scandalized by his paradoxes.

The Revolution of 1848 and the democratic conquests—notably that of universal suffrage—which it sanctioned, powerfully drew public attention toward questions of a political and economic order. The name of Louis Blanc deserves especially to be cited here; and the celebrated conferences at the Luxembourg, over which he presided, exercised a powerful influence not only on the state socialists, who shared his opinions, but on men of distinctly different outlook, like Le Play.

As might have been expected, the political regime instituted after the *coup d'état* of 1851 was not favorable to the development of the social sciences. They received new momentum only when, with the decline of the empire, the great liberal minister Victor Duruy was

placed in charge of public instruction. Unfortunately the efforts of Duruy were openly or secretly thwarted. He was unable to carry through his plan for a section of juristic and economic science at the Ecole pratique des Hautes Etudes, which he founded in 1867. His only important creation in this realm was the establishment at the Collège de France of a course in the history of economic fact and doctrine, in charge of Levasseur.

In the course of the last half century the progress made by the social sciences in France, in the domain of teaching and also in public influence, has been reflected in a number of important innovations. These innovations have most frequently resulted either from social movements or from theoretical discoveries, exactly as in the course of the preceding century. Three events in the history of the Third Republic have especially contributed to the progress of the social sciences—the Franco-German War, the Dreyfus affair, and the World War. Each of these led to the creation of more or less important institutions. Following the Franco-German War the Ecole Libre des Sciences Politiques was founded, on the initiative of a man of large and penetrating views, Emile Boutmy, with the encouragement of Taine. This institution, as its name implies, took for its object the construction of the framework of French administration by means of the study of social facts. The Dreyfus affair, which shook the whole of France about the year 1900, provoked an important change in political orientation and at the same time a quick revival of interest in the social sciences. It expressed itself mainly in an intense movement to popularize social ideas and in a tendency to give greater prominence to the social factors in phenomena of every order. With this movement of ideas should doubtless be linked the meeting at Paris, in the year 1900, of the first international congress for the teaching of the social sciences, the establishment of an international library of the social sciences, and the creation of an Ecole des Hautes Etudes Sociales, founded in Paris on the initiative of Mlle. Dick May. The influence of the World War on the development of the social sciences was twofold. In the first place it drew eager attention to the relations between peoples and to all the problems involved in the League of Nations. As a result there came into existence not only numerous publications relative to the organization of peace, but various scientific institutions, some

French, like the *Ecole des Hautes Etudes Internationales*, founded in 1921 in connection with the law faculty of Paris, others of an international character, such as the Institute of International Law, or the Academy of Comparative Law, whose seat is at the Hague. In the second place, the events of the war and of the post-war period stressed the importance of economic factors and financial questions, and led to the multiplication of works and of periodical publications in this domain, as well as to the creation of new chairs of political economy and of finance in most of the institutions of higher learning.

In addition to the influence of these acute crises one must note the less easily distinguishable influence exerted on the progress of the social sciences by the sense of latent crisis which the machine age has, perhaps permanently, brought in its train. The parallel progress of capitalism and of socialism in France, and the elevation of syndicalism to a doctrine about the year 1900, combined powerfully to attract the attention not only of the masses, but of investigators, to an entire series of problems which, at about that period, were designated under the rather vague label of the "social question."

With varying sentiments and often with insufficient technical preparation, many thinkers attacked these problems with the object of resolving class antagonisms. There were socialist scholars who found their principal means of expression in a center of instruction, the *Ecole Socialiste*, and in the periodical, the *Revue socialiste*, founded in 1880 by Benoit Malon and interrupted by the war. The *Ecole Syndicaliste* had as its organ for several years the *Mouvement socialiste* of Hubert Lagardelle. More recently the communistic solution found expression in the *Revue communiste*, founded in 1920. On the opposing side the class in the moral and political sciences at the Institut de France remained for a long time the citadel of individualistic liberalism. Since then the institute has become hospitable enough to other schools of thought. The same kind of tolerance prevails in the domain of higher education. It is no longer accurate to say that the economic instruction of the law faculties or of the Collège de France spreads the so-called "classical" doctrines, as was the case during a certain period.

Between the two camps the Christian socialist movement, heir to the liberal and proletarian Catholicism of Lamennais, sought a solution

of social conflicts in the inspiration of the Gospels. This movement, alternately encouraged and disowned by the Holy See, continues to play a not unimportant role in political and social life. Its two principal organizations are the Sillon group, directed by its founder Marc Sangnier, and the *Semaines Sociales*, dedicated to the study of social problems.

Here should be mentioned the school of social conservatism inspired by Le Play, which exerted strong influence during the years 1860 to 1890. With this is associated the Musée Social, of which we shall speak again later on. The school of Le Play had as its principal periodical the *Réforme sociale*, founded in 1881 and directed by Demolins, continued since 1886 as the *Science sociale*.

As for the official instruction of the church, dispensed by its institutions of higher learning—notably in the Institut Catholique of Paris and the Faculté Libre du Droit at Lille, which in 1893 created a section of social and political science—it manifestly oscillates between these different trends. While certain professors agree with Le Play's individualism, or at least with his emphasis on the family, others like Boissard are frankly state socialists, and still others, like Paul Bureau, have tried to reconcile the two tendencies.

It would be possible to measure the influence which the works of scientists have exerted on the development of the social sciences, but this lies beyond the scope of the present discussion. We shall confine ourselves here to one of the theoretical efforts that has had the significance of a historic event for our sciences. We refer to the work of Emile Durkheim, professor of sociology at Bordeaux and later at Paris. Bringing his thought to bear on the very object and method of social science, he elaborated a doctrine with which were aligned more or less completely a certain number of philosophers, jurists, historians, economists, linguists, anthropologists and psychologists. This means that his influence radiated through all branches of social science. Durkheim and his disciples formed a coherent group whose influence on their contemporaries was powerfully served by a periodical, the *Année sociologique*, a collective product inspired by the spirit of positive and critical science, which appeared from 1896-97 to 1913 and began the publication of a new series in 1925.

The theories of Durkheim, attacked at first not only by philosophers but also by sociologists

like Tarde, who were fundamentally individualistic in spirit, are still debatable. Nevertheless no one questions that they represent at the present time the most vigorous and coherent effort to study human societies yet made in France. The title "French School of Sociology" can legitimately be conferred upon those who work in this spirit.

II. Let us examine now, from the standpoint of the present, the state of the social sciences in French speaking countries, and the place they occupy in higher education and in culture generally.

The social sciences in France have become too differentiated to admit of instruction conveying new results under the name of sociology. And it is just this fact, which we mention in passing, that contributed temporarily to the discrediting of the very notion of sociology. There was a time when certain pseudo-scientists bestowed upon themselves the title of sociologist, and learnedly enunciated pretended social laws which were quickly contradicted by more serious research. We have passed beyond that, fortunately. It does not follow that the teachings of general sociology are useless. Quite the contrary is true, but those who present these teachings no longer consider themselves obliged, or even authorized, to include the whole vast realm of the social sciences. Sometimes they seek the most general features by which to grasp these sciences and then proceed to construct a course in social methodology or morphology; or again they take a definite subject which they choose by reason of their own individual training, or of their particular personal preferences, and treat it in its methodological bearings. Chairs of sociology are quite rare. They are absent from the law faculties. There is one in the faculty of letters at Bordeaux and another at Toulouse, but there are no others in the provinces. Paris is somewhat better equipped. The Sorbonne has one; there is, besides, a course of sociology at the Institut d'Ethnologie. The Collège de France has a chair of social philosophy. Finally a course in sociology is given at the Institut Catholique and at the Ecole des Hautes Etudes Sociales. Students of sociology in France find a general medium for discussion in the *Année sociologique*, founded by Durkheim. The publication of this periodical was interrupted by the war and by the death of its founder, but was renewed in 1925 under the direction of Marcel Mauss. Around it, about the same time, a

scientific society was formed—the Institut International de Sociologie, whose members are for the most part collaborators on the *Année*. Kindred in conception but divergent in spirit and opposed to the ideas of Durkheim, the Société de Sociologie, which was organized in 1895 on the initiative of René Worms, publishes a periodical, the *Revue internationale de sociologie*, directed by G. Richard, professor in the faculty of letters at Bordeaux.

Leaving general sociology and passing to the study of the various individual social sciences, an initial difficulty awaits us. It concerns philosophy. To consider as social sciences all the branches of philosophy would be impossible. Some of them obviously include no social element. The question of social content presents itself only in the fields of ethics, psychology and pedagogy. In each of these sciences there is still an animated controversy between the individualists and the "sociologists." Each side, perhaps, could be given its due, for there are individual and social ethics, individual and social psychology, and individual and social pedagogy. Ethics considered from the social point of view has benefited especially from the work of Lucien Lévy-Bruhl (*La morale et la science des mœurs*, Paris 1903). A. Bayet has traced the historical development of ethics in a course of lectures given for the first time in the Ecole Pratique des Hautes Etudes in 1925. Social psychology is taught, notably by Halbwachs and Blondel, in the faculty of letters in Strasbourg. Finally social pedagogy, taught at the Sorbonne by Durkheim's successor Fauconnet has been a subject to which Binet, Simon and others have devoted themselves. The Musée Pédagogique, founded at Paris in 1894, is the center for all information concerning methods of instruction. In another Paris museum, of kindred purpose, an institute of professional orientation has been functioning for two years. It has two regional offices in the provinces. In this connection it should be noted that the new methods in experimental education (and in a general way all the rationalistic procedures, with the somewhat mechanical rigidity they require) find in France, which is a strongly individualistic country, less favorable ground than almost anywhere else.

In approaching history we find the same difficulty that confronted us in philosophy. Is history a science and, if it is one, is it a social science? Historians are, or are not, sociologists according to their intellectual tendencies, their

initial training, the subjects they study. They are far from agreement among themselves as to the place which should be reserved for collective forces and ideas. About 1900 the *Revue de synthèse historique* published a celebrated discussion of this subject which emphasized this fundamental disagreement. The historians Seignobos and Mantoux, the economist Simiand and the philosopher Rauh participated in it. Differences of opinion on the subject are still rife. The difficulties involved make it impossible either to include history among the social sciences or entirely to exclude it. To take an example, certain historians of Greek and Roman antiquity, like Gernet in Algiers, Glotz in Paris, Piganiol in Strasbourg, and others, allow a considerable place for social facts, while many of their colleagues—the larger number it seems—are inclined to envisage history as a succession of particular events. The same is true among historians of the Middle Ages and also among modern and contemporary historians. There are only three branches of history where the nature of the material compels the student to envisage facts from a social point of view, thus making a sociologist of him without his being aware of it. These are to be found in the domain of law and institutions, of religion and of ethnology.

The history of law in the larger sense includes also the history of institutions through ancient, mediaeval and modern times. Instruction in it is given especially in the law faculties, where the programs of study, after having for a long time disregarded it, now properly grant it a prominent place in the curriculum. Roman law is the only ancient juristic system taught. It is compulsory in the program of the first two years and in the studies required for the degree of Doctor of Laws (diploma of advanced study in private law). The other branch of historical instruction in the law faculties is that of French law, taught to first year students and to candidates for the doctorate (history of public law for the D.E.S. of public law, history of private law for the D.E.S. of private law). This instruction is given by professors known as Romance historians, averaging about three in number in the thirteen law faculties of the provinces and eight in the law faculty in Paris. The Paris faculty possesses, besides, a chair in the history of canon law which is duplicated at the Ecole des Hautes Etudes. For the sake of completeness it should also be mentioned that instruction in constitutional law

allows an important historical division, and that the chairs of comparative legislation which exist in some faculties, notably in Paris, are now occupied by incumbents who are permitted to give courses in the history of foreign law.

The law faculties are not the only ones which include the history of law. There are faculties of letters in which the history of Roman and of French institutions is taught concurrently, though from a somewhat different angle and in programs which change every year. Faculties are rare that do not provide instruction in Greek institutions, at least in outline. The Ecole des Chartes has a chair of French law and of canon law, occupied for a long time by Paul Viollet. Babylonian and Assyrian law is expounded at the Collège de France by Fossey and at the Ecole des Hautes Etudes Sociales by Scheil. France, remembering that she is an Islamic power, disseminates rather widely the study of Mohammedan law. This is taught in the Algiers faculty of law by Morand, and in Paris at the Ecole Coloniale and at the Ecole des Langues Orientales by Milliot. At the Collège de France a chair of Mussulmanic sociology is held by Massignon. The institutions of mediaeval England form the subject of a course of study at the Ecole des Hautes Etudes Sociales under Joüon des Longrais, the successor of Bémont. Contemporary Chinese law is expounded by Escarra at the Ecole des Hautes Etudes Chinoises, while in the same establishment Granet in his course studies ancient Chinese institutions.

That two courses in this domain have been eliminated must be noted with regret. The lectures at the Ecole des Hautes Etudes Sociales in which Thévenin studied Frankish law, proceeding thence to Germanic law, were not continued after his death. On the other hand the chair of comparative law of the law faculty in Paris has not proved a substitute for the chair dedicated to the study of comparative legislation at the Collège de France, discontinued at the death of J. Flach. The object of the two courses of instruction is not the same: the courses in the faculty of law have as their aim the comparative study of contemporary legislative systems, while the instruction at the Collège de France had in view rather the comparative study of ancient systems of law and, with the writings of some rare jurists in the field of comparative law, such as Rodolphe Dareste, was the only equivalent in France of the German *vergleichende Rechtswissenschaft*.

French interest in the history of law is manifested not only by teaching faculties but also by scientific societies specifically dedicated to this study. Chief among them is the Société d'Histoire du Droit, of which Paul Fournier is president. Similar groups exist in the provinces: the Société d'Histoire du Droit Normand at Caen, and the Société d'Histoire du Droit des Pays Flamands, Picards et Wallons at Lille. As for publications, it is out of the question to attempt to give even a summary list. We shall content ourselves here, and also when we reach the other social sciences farther on, with indicating the most important scientific periodicals. The leading journal dealing with the history of law is the *Revue historique de droit français et étranger*, founded in 1855.

Instruction in the history of religion is more or less centralized in Paris in the division of the Ecole Pratique des Hautes Etudes which has been especially dedicated to it. This division was created in 1886 in spite of the opposition of those who feared that scientific investigation was sacrilegious. Most of the religions practised today or in antiquity are studied objectively there, from the religion of uncivilized peoples (Mauss) to the history of Christian dogma (Alphandéry). Nevertheless at least one lacuna is noticeable in the lack of attention to the history of the Protestant religion. Among the courses of instruction at the Collège de France there are several which touch closely upon religious history: Loisy's on the history of religion, Moret's on Egyptology, and Sylvain Lévi's on Hinduism. The provinces are very badly equipped in this respect, and faculties of letters that give instruction in the history of religion are rare. One can cite only Strasbourg (Alfaric), Lille (Jeanmaire) and Aix (Toussaint).

There would be some injustice in failing to notice that the institutions of higher learning founded by the different churches almost always give an important place to the history of their own religion. This tendency is marked in connection with the Institut Catholique in Paris; the faculty of theology in Strasbourg; the faculties in Lyons, Lille, Toulouse and Angers which are independent of the official university system of the state; and certain *grands séminaires*. For Protestantism it can be seen in the faculty of Protestant theology in Paris, likewise independent. However remarkable the instruction given in these institutions may be on occasion, they will always, rightly or wrongly, be suspected of fostering apologetics.

A number of scientific societies have been organized for the study of the history of religion. The most important is the Société Ernest Renan, founded in Paris. The Ecole des Hautes Etudes Sociales publishes at irregular intervals a collection of the writings of its teachers and of its best pupils under the name, *Bibliothèque de l'école pratique des hautes études* (religious sciences). There is likewise a special periodical, the *Revue d'histoire et de philosophie religieuses*, founded in 1921. The study of religious origins has been enriched by a special museum built in Paris in 1885 and named after its founder, a Lyons merchant, Guimet. This museum, dedicated especially to iconographic representations of oriental religions, is directed by J. Hackin.

For reasons at once theoretical and historical, ethnology has remained, for the French school especially, the favorite stamping ground of sociology. Nevertheless, down to these last years, the teaching of ethnology remained somewhat scattered. In 1924, on the initiative of L. Lévy-Bruhl, an Institute of Ethnology was formed, in association with the University of Paris, intended to group and to coordinate the various branches of ethnology, ethnography, anthropology, technology, linguistics, study of animal societies, etc. The ensemble forms a cycle of studies for which a diploma is issued. Two scientific societies, the Institut Français d'Anthropologie, founded in 1911, and the Société d'Ethnographie, founded in 1859, have made the study of ethnological questions their special task. As for periodical publications, since the disappearance of the *Revue des études ethnographiques et sociologiques* only the *Anthropologie* remains. Ethnography, one of the branches of ethnology, has its museum, founded in 1895 and located at Paris in the Trocadéro Palace. It is directed by Dr. P. Rivet.

Passing on to the consideration of law as a social science, we find, as is natural, that it is taught mainly in the faculties of law. The subject is traditionally divided into private and public law, the former customarily including penal law and civil procedure which touches public law at certain angles. It enlists the services of a numerous personnel of professors or instructors (averaging six in each of the provincial faculties, fifteen in Paris). Civil law is given most prominence. At its side are ranged commercial and maritime law, criminal law, private international law and, in certain faculties, insurance, registering and compara-

tive law. This last branch of instruction is developed especially at the University of Lyons, where an institute of comparative law was created in 1922. The accepted methods of instruction in the law faculties have been modified and rendered flexible during the last half century, especially since the World War. They now more nearly approach the practise of the other faculties. If the professor still conducts his course in robes, this practise is almost the last vestige of their particularism. Indeed since the thoroughgoing reform of 1924, which consisted, above all, in the introduction of written compositions into the examinations, the course of study has become more difficult and more serious, and the student who "does his law" without serious work, a common type formerly, runs the greatest risk of failing in his examination. Contacts between student and professor are more frequent and more direct. Study rooms have been multiplied; direction of theses and of work has become more effective. To put it briefly, in this domain, also, instruction tends to become an initiation of youthful spirits into new disciplines and methods, rather than an effort to communicate revealed truth. At the same time, by a parallel evolution, the foundation of the instruction itself has become modified. The exegesis of the codes has been replaced by the study of juridical facts. The professor no longer considers the statutes as the only facts worthy of his attention. He directs his glance to the decisions of courts of justice and even to humble practise, and finds in them social facts which merit his observation.

While instruction in civil and penal law is given almost exclusively in the law faculties, certain branches of private law are taught elsewhere. Commercial law, for instance, is taught at the Conservatoire National des Arts et Métiers and at the Ecole des Sciences Politiques, not to mention the Ecoles Supérieures de Commerce, where instruction is given which perhaps rivals that of the faculties, and which is often given by the same teachers. Private international law is taught at the Ecole des Hautes Etudes Internationales. Among the scientific societies engaged in the study of private law or of certain of its elements, may be cited the Société des Etudes Législatives, founded in 1901, which undertakes to facilitate the task of parliament by aiding it in the drafting of legislation; the Société de Législation Comparée, founded in 1869, whose title sufficiently indicates its object; and finally the ancient and

celebrated Société des Prisons whose field of action overlaps that of penal law. In the provinces the Académie de Législation of Toulouse should not be forgotten. Periodicals devoted to private law are sufficiently numerous in France. We shall name only the most important. The *Revue générale de droit* bears at once on private and on public law. In the field of private law the *Revue critique de législation et de jurisprudence* deserves mention. The *Revue trimestrielle de droit civil*, founded in 1903, specializes in civil law; the *Annales de droit commercial* in commercial law; the *Journal de droit international privé* (founded by Edouard Clunet) in private international law. Along with these reviews should be noted the jurisprudence collections, or case books, in which many of the decisions emanating from the most important courts and tribunals are published and commented upon by professors of law and by jurisconsults. Several of these collections exist: the most celebrated are *Le Sirey*, started in 1831, and *Le Dalloz*, started in 1845.

The comments made above on private law apply equally to public law. Here also we witness a rejuvenation of methods in the exposition of the subject and in the doctrine itself; general public law, constitutional law, administrative law, public international law, public finance are taught in all the state law faculties, and most of them in the independent faculties as well. But it is especially the Ecole Libre des Sciences Politiques which here competes with the university. The preparation for high administrative positions (state council, diplomacy, inspection of finance, etc.) is very well organized there, and certain courses of instruction, such as the history of political ideas and doctrines, are given which one would seek in vain on the bulletin boards of the law faculties. In addition a whole series of courses, too numerous to list, allows a student to become acquainted with most of political science, without any serious lacunae. Public international law, which since the war has received such a sudden impetus, does not yet seem to have been given the place to which it is entitled in French law faculties. Instruction in it is still optional (but without doubt it will become obligatory before long). In any case this science is extensively taught at the Ecole des Hautes Etudes Internationales, an institution associated with the law faculty of Paris. The law of nations is likewise taught at the Ecole Libre des Sciences Politiques, not to mention such inter-

national schools as the academy at the Hague. Scientific societies properly called French, having as their aim the objective study of problems of public law, do not exist so far as we know. One could not thus describe the existing political groups, formed within the Parliament and outside of it, despite the generally high level of the work done there and the great value of some of it. The principal scientific reviews dealing with public law are the *Revue du droit public et de la science politique* (1894), and the *Revue de science et législation financières* (1903), both edited by Gaston Jèze, and the *Revue de droit international public*, edited by Geouffre de Lapradelle, Alvarez and Politis.

Among the social sciences political economy is without doubt the one in which widespread instruction has been most neglected. It took the stubborn efforts of Leveillé, about 1880, to gain an honorable place for it in the law faculties, and for a long time it was not treated in a truly scientific way. In this connection the Paris faculty seems to have been outdistanced by some of the provincial faculties. In any case the time has passed when instruction in political economy can be treated with disdain. The World War and its consequences have sharply drawn the attention of the public to the primordial importance of economic phenomena in modern societies. In the law faculties economic instruction is given by an average of three professors in the provinces and by fourteen professors in Paris, but public interest in economic questions has reached such a pitch that the number of teachers provided is no longer sufficient, especially in Paris, where the number of candidates for the economic doctorate already appreciably surpasses the number of aspirants for the degree of doctor of laws. This department of instruction comprises general political economy, the history of economic doctrines, working class legislation, rural legislation and colonial legislation. Certain faculties have courses in mining or public works legislation. Instruction in statistics, well organized in Paris in an institute of statistics, is unfortunately not given, so far as we know, in any of the provincial law faculties.

The law faculties are not the only places where economic science is taught. The Conservatoire National des Arts et Métiers possesses a chair of political economy, the oldest in France, made famous by the names of J. B. Say and of Blanqui, and at present occupied by F. Simiand. It has, besides, a chair of industrial

economy and of statistics (Liesse), another of economy and social insurance (Mabilleau), a chair for the study of the organization of labor and of workingmen's associations (Aucuy), and finally a chair of economic geography (Hauser). The Collège de France likewise accorded quite an important place to economic science when it provided a chair of history of labor (G. Renard), a chair of cooperation (Charles Gide), a chair for the study of economic and social facts (Marion), and a chair of social work (Fuster). The Ecole Pratique des Hautes Etudes includes a department of economic history, too fragmentary a realization of the idea of Victor Duruy. This department of study is under the charge of Landry, Simiand, Pirou, Bourgin and Mathiez. At the Ecole Libre des Sciences Politiques numerous branches of economic instruction are represented. Finally we should add that a chair of political economy has existed at the Ecole Nationale des Ponts et Chaussées since 1846. Another chair may be found at the Ecole des Mines, and the Ecole Polytechnique has had since 1902 its chair of social economy. It is perhaps in the field of economics that scientific societies have developed most vigorously within the last few years. There are numerous groups that have set themselves the task of studying economic phenomena in their various aspects, but most of them are not of a truly scientific character, completely free from political, philanthropic or economic bias. We shall note only the Société de Statistique of Paris, founded in 1860, the Société d'Economie Politique, founded in 1842, and finally the Centre de Documentation Sociale, established at the Ecole Normale Supérieure. The principal French economic periodicals are the *Revue d'économie politique*, founded in 1887, the *Journal des économistes* and, in a more specialized branch of economics, the *Revue bancaire*. Economic history likewise has its periodicals, the *Revue d'histoire économique et sociale* and the *Annales d'histoire économique*.

Somewhat on the margin of political economy is urbanism, a new science, social *par excellence*. It is taught according to a simple formula, sufficiently recognized today, in an Institut d'Urbanisme (1925) associated with the University of Paris, and instruction there is given not only by economists but by professors of public law, by administrators, by architects.

Colonial questions are systematically studied in a special school, the Ecole Coloniale, as well

as in the law faculty of Paris and in the Ecole Libre des Sciences Politiques.

This rapid enumeration can not give any real idea of the present state of the social sciences in France. In order to complete the record many features would have to be added. Thus social hygiene and legal medicine, social sciences of the first rank, should have figured in it. They are taught in the faculties of medicine. In addition there is a chair of hygiene and the physiology of work in the Conservatoire National des Arts et Métiers.

It should be very clear from this exposition that the social sciences in France occupy an increasingly large place in the intellectual life of the country and require the efforts of a constantly growing body of investigators. At the same time it is evident that instruction in the social sciences is a thing of shreds and patches dispensed in various institutions by diverging methods and with differing, not to say opposing, purposes. If conformity in the social sciences means sterility, we in France are in no danger of suffering from this defect, and the time is still distant in this country when faculties of social science will be founded that shall be real institutions of higher learning divorced from all preoccupation with professional training.

III. To measure with precision the place occupied by the social sciences in public opinion would require a long and minute inquiry. In particular the curve of their progression would have to be established by means of a large number of charts and figures dealing with these sciences. There is no possibility of doing this statistical work here, even though at present it is facilitated by a very useful instrument, Grandin's *Bibliographie générale des sciences juridiques, politiques, économiques et sociales* (3 vols., Paris 1926).

Social science is elaborated for the most part in the scientific institutions of which we have spoken. One can do no more than point out some of the means by which it is spread and popularized. The first of these, and one of the most efficacious, is primary and secondary instruction. General sociology made its entrance into the programs of the normal schools as a result of the persevering efforts of Paul Lapie, a clear sighted administrator who was at the same time a philosopher-sociologist. The primary schools and *lycées*, though their programs are apparently unmodified, are making room for the social sciences through a kind of internal

evolution. The teaching of history tends to bestow an increasingly large amount of attention on the institutions of different peoples. Geography, formerly exclusively physical or political, is giving place to economic and human geography. Under the name of civic instruction public law is explained in history and philosophy classes, and the day is doubtless not far off when children will be made familiar with the principal ideas of political economy.

Graduate and technical instruction in all its forms has developed extensively in France since the Great War, and necessarily yields a certain place to the social sciences in its programs. However, there is an entire series of gradations observable between some village school-room, with its humble evening course, and such a rich, powerful institution as the Ecole des Hautes Etudes Commerciales in Paris, where the level of instruction is almost on a par with that of the faculties, and the teaching is often done by the same instructors.

Workers' education in the early years of the century gave birth to numerous *universités populaires* where scholars came to expound scientific questions. This was no more than a fire of straw, for the instruction, dispensed with more zeal than method, was ill adapted to those who came to receive it. The problem of workers' education has been taken up on a new basis, and is being carried forward in the *bourses de travail* under the aegis of the syndicates. It goes without saying that, especially since the war, economic, social and political questions have most frequently formed the subject of lectures, and have attracted the most eager audiences. Another institution similarly concerned with problems of workers' education is the Ecole des Coopérateurs organized by the Fédération des Sociétés Coopératives de Consommation.

Among the institutions in Paris which have set themselves the task of popularizing social science, we must mention the Collège Libre des Sciences Sociales and the Ecole des Hautes Etudes Sociales. The first, founded in 1895, comprises courses of study divided into three sections: historical studies, theory and method, and technology. The Ecole des Hautes Etudes Sociales, founded in 1900, comprises five sections: social science school; school of philosophy; school of journalism and of preparation for public life; school of advanced international studies; school of art. In the provinces we may mention the Institut des Sciences Sociales

at Lille, founded in connection with the university, which each year gives series of public lectures and confers the diploma of doctor of social science. It would be futile to try to enumerate all the discussions and lectures on social subjects. They are of all kinds and all colors, from popular lectures, or a discussion in the *Annales* by some academician who happens to be in vogue, down to the educational lecture given by some candidate during an electoral campaign. Related in idea and daily increasing in power, the press spreads popularized notions of social science among the public. Here again it is impossible to give precise details which would, at best, often prove misleading. It suffices to compare a daily newspaper of today with an issue of the same paper thirty or forty years ago, and to note the increased space given to social problems, foreign politics and economics. To name all the reviews which in this field occupy an intermediate place between the scientific periodical and the newspaper would be dull and uninteresting. We shall content ourselves with citing those of a particularly technical character, such as, in political science, the *Revue des sciences politiques*, published since 1886, and the *Revue politique et parlementaire*, founded in 1894; in economics, the *Information sociale*, which in 1922 succeeded the *Information ouvrière et sociale*; the *Revue des études coopératives*, founded in 1921; the *Documents du travail*, which have been appearing for twelve years and serve as the organ of the Association Française pour la Lutte contre le Chômage et pour l'Organisation du Marche du Travail.

A last means of propagating ideas in the social domain is the museum. This assumes two forms, the temporary exposition and the permanent museum. Neither form is very popular in France. Without doubt the universal expositions held in Paris—notably that of 1867 under the impetus given by Le Play, but the following ones as well, in 1878, 1889 and 1900—did accord a large place to social institutions, but for the last thirty years no exposition of this size has taken place, and the smaller expositions do not seem to have aroused a lively public interest. As for museums strictly so called, one must not, despite its name, consider as such the Musée Social, founded in 1896 by the Count of Chambrun. It is something entirely different—a center of information, of documentation and of truly scientific inquiry. The only institution which answers the defini-

tion of a real social museum is that of the Conservatoire National des Arts et Métiers, which is, above all, of historic interest.

IV. Instruction in the social sciences in Belgium is well developed, and succeeded at an early date in arousing public interest. As far back as 1830 political economy had been taught in the two state universities (Ghent and Liège), and in 1862 an association, international it is true, was created in Brussels under the patronage of Lord Brougham, Garnier Pagès and Michel Chevalier for the purpose of promoting progress in the social sciences. At present the study of these sciences is being actively furthered in each of the four universities (Ghent, Liège, Brussels and Louvain).

The fact that the teaching of the social sciences flourishes in Brussels is largely due to Ernest Solvay, a man of vision, at once an industrialist and a sociologist. In 1889 he founded an *Ecole des Sciences Sociales*, which was reorganized in 1901 and is at present an integral part of the University of Brussels. This school comprises twenty-two courses given by fifteen titular professors and divided into three sections (political, economic and social science). The Institut de Sociologie, also founded by Solvay (1901), publishes documents and is provided with a rich research library. It is a center of both instruction and research.

Among Belgian scientific societies devoted to the study of the social sciences, the most important is, beyond question, the Académie Royale de Belgique, with its section in the division of letters devoted to the moral and political sciences.

Switzerland is original enough to possess at Geneva a faculty of the economic and social sciences which forms no part of either the faculties of letters or of law. The following subjects are taught there: sociology, political economy, economic history, statistics, commercial economics, commercial technique, commercial law. There exists, besides, in Geneva, a special institution called the Institut J.-J. Rousseau, founded in 1899 and dedicated to the study of psychology applied to professional orientation. Geneva is also, as need hardly be added, the seat of numerous international institutions.

III

Germany

From the days of Thomas Aquinas, economic life was included in that complex of human experience which every *summa* and many scholastic monographs sought to organize and classify. The customary lectures on the moral sciences discussed economics side by side with political theory. Both of them were taught, however, merely as a part of the prevailing religious world outlook, observed facts being considered mainly from the standpoint of their compatibility with the teachings of the Bible, of the church fathers and of Aristotle.

Mercantilism, the economic doctrine of the new absolutist state, marked the transition of the discipline from theology to science. Not until the second half of the seventeenth century, however, did it produce a distinguished representative in the person of Johann Joachim Becher, and only in the first half of the eighteenth century did it gain admittance into the universities. Cameralism, the German variety of mercantilism, considered economic and financial questions primarily from the standpoint of the *camera*, or the prince's household. Nevertheless it produced some theoretical discussions and achieved conclusions which anticipated many of the doctrines of the English classical economists. While this is true for Johann Heinrich Gottlob von Justi and in a limited measure for Hörnigk, it by no means applies to economics as a university discipline. There economics, like politics and ethics, was taught as a part of practical philosophy and, in Schreber's words (1764), presented little more than a system of precepts for the master or the mistress of a household, for children and servants. Although Leibniz had already strongly emphasized the importance of economics and Thomasius had insistently demanded the establishment of an economic professorship, it was not until 1727 that a separate *Profession in Oeconomia, Policey und Cammersachen* was founded at the University of Halle. Even then the intention was not to develop a science of economics but to promote the training of state officials. Frederick William I, who established in the same year an economics chair at Frankfort on the Oder, considered eco-

nomics as the science of rational management of both private and public economic affairs. He hoped to remedy the evil of "poor economy" practised by many youths who were burdened with debts at the completion of their university terms; at the same time he favored such "politica, oeconomica und cameralia" as might be really useful as an indispensable preparation for the academically trained administrator in the age of mercantilism.

A more intensive study of economics at the universities and an increase in the number of professorships came only gradually and after numerous setbacks. It is significant that for some reason (probably his refusal to embrace Catholicism) Justi failed in 1752 to receive a position intended for him at the Vienna Theresianum, and though as police commissioner of Göttingen in 1755 he was allowed to give lectures, this teaching appointment was conferred only two years later upon a professor of natural history and chemistry. However, it is important that Germany had six professorships at the time when the physiocrats brought about the establishment of the first chair of economics in France. In the last quarter of the eighteenth century the increase in Germany was more rapid, so that by 1798 twenty-two higher institutions of learning had chairs of economics.

Although the physiocrats had remarkably little effect upon science in Germany, yet indirectly their writings provided the stimulus for the founding of the first school of cameralistics, the Kameral-Hoheschule in Kaiserslautern in 1774. Despite the hearty welcome given it by the *Ephémérides du citoyen*, this was not as yet a school of economics in the modern sense. Coordinate with, indeed superior to, the professor of agriculture, commerce, finance and administration was the professor of natural history, chemistry, pure and applied mathematics, architecture and mining. Instruction took no cognizance of the new tendencies in science but was still guided entirely by the old cameralistic aims. Nor did the removal of the institution from Kaiserslautern to Heidelberg effect any change. The establishment of an economics

faculty at the University of Giessen seemed of greater promise, for the government of Hesse summoned the most distinguished German physiocrat, Johann August Schlettwein, to the newly founded chair of economics. But his activity there lasted only for about a decade (1777-85); moreover he was not essentially successful there as he had been earlier at Karlsruhe and Basel. Since all attempts to develop German economic science thus died in their infancy, it remained for the *Wealth of Nations* to make the decisive break and to launch modern economics in Germany as elsewhere. The adaptation of Adam Smith's economic principles and the controversies they aroused determined the fortunes of economics in German universities for nearly a century.

Like Quesnay and his followers in France and Ricardo and John Stuart Mill in England, the great German economists also lived outside the universities, and were indeed often antagonistic to them. Johann Heinrich von Thünen developed and applied his doctrine of localization as a practical agriculturist. Karl Rodbertus was likewise a Prussian landowner. Friedrich List, the gifted opponent of cosmopolitan classical political economy, did, to be sure, teach at the University of Tübingen for a short period in his youth; but at the time he wrote his treatise and the great political essays, he had no official or professional standing and found academic science no less hostile than bureaucratic politics. Karl Marx early gave up the idea of qualifying as professor and in his theoretical writings he sharply attacked university science; the universities in their turn ignored his contributions to theory and banned him for decades on account of his hostility to the state.

The peculiar course of German economics since the forties has been largely determined by the fact that when opposition to the classical school developed among the professors, it was based on methodological and philosophical grounds propounded by the historical school rather than on specific theoretical disagreements like those of F. B. W. von Hermann, Theodor von Bernhardi or H. K. E. von Mangoldt. Ranke and Savigny, Jakob Grimm and Otfried Müller were the spiritual descendants of Herder and the romanticists, who among other things aroused the feeling for natural "organic" growth of an individual and of a nation, and who substituted for a mechanistic explanation an organic-intuitive "understanding" connected with an appreciation of the intangible forces of nation-

ality and national spirit. This new method of historical interpretation, which was developed first in other sciences, provided subsequently the necessary impetus for economics as well. From this vantage point Karl Knies, Wilhelm Roscher and Bruno Hildebrand recognized the weakness of the classical position, its lack of a historical sense, its consequent "cosmopolitanism" and "perpetualism" and conceived in broad outlines a program of "political economy from the standpoint of the historical method" (Knies, K., *Politische Oekonomie vom Standpunkt der geschichtlichen Methode*, Brunswick 1853, 2nd ed. 1883).

After the appearance of these three men, the so-called historical school of political economy held almost undisputed sway at the German universities down to the end of the nineteenth century. The content of instruction, however, did not remain stable. It experienced a significant change with the rise of the younger generation of Schmoller and Wagner, Brentano and Knapp, Held and Gothein, who combined political inferences and recommendations with their historical knowledge to a greater extent than their predecessors. The usual lecture on practical political economy often became a lecture on economic politics in more than name; norms of economic policy and even of social policy formed an important part of the lecture content. Because the classical theory was seen to be inconsistent with historical or contemporary life, and because the continuance of social misery was known to threaten state and society with revolutionary cataclysms, it was inferred that the task of science is not only to explain but also to solve the social problem.

This new trend of university economics, which its opponents characterized as "socialism of the chair," did not lead to a reorganization of the faculties nor to a specialization of professorships in distinct disciplines. Financial arrangements provided for continuous functioning of only two full professorships at any but the large universities of Berlin and Munich and hence forced the professors to give successive large lecture courses on general and practical political economy, finance and later also on economic history, in addition to occasional special courses which were ordinarily left to instructors of lower rank. However, this was merely one factor in the situation. More important in the present context is the fact that since all courses had history as their common basis, the need of specialization appeared less urgent than in the

Anglo-Saxon countries. The usual course of theoretical economics given by adherents of the historical school, and also by theorists like Adolf Wagner, propounded not abstract doctrines but a historical and sociological economic theory. The relation between theoretical and practical economics was therefore not one of complete contrast and mutual exclusiveness in subject matter; on the contrary, the latter made practical application and drew conclusions on matters of policy from the teachings of the former.

Intensification, not specialization, was therefore looked upon as the method for the further development of teaching and study. This was the purpose of the seminars which were organized to supplement lectures in the middle of the last century and which served above all to unite upper classmen and their teachers in working groups. The seminars of Hildebrand, Knies and Ernst Engel of the older generation and, more recently, those of G. F. Knapp and Gustav Schmoller attained to eminent distinction as centers of scientific training.

For a multiplicity of reasons the first decade of the twentieth century marked a change and inaugurated a transformation in faculties, in subject matter and in methods of instruction, a process which is still in progress. The impetus came from a group of scholars who, under the leadership of Max Weber and Werner Sombart, attacked the confusion of ethics, politics and economics characteristic of both the older and the younger historical schools and espoused the cause of emancipating the social sciences from value judgments. This movement was the inevitable result of the thorough inculcation of the relativity of all values by the historical school. With the laying bare of historical roots and limitations of all values, all divergent value judgments seemed equally justifiable and comprehensible. Therefore science could be kept out of the conflict of opinions, philosophies and parties only if every judgment of value were tabooed as unscientific. It was no accident that the old names "Volkswirtschaftslehre," "Nationalökonomie" and "Politische Oekonomie" became objects of suspicion. To be sure they were not entirely superseded. It is significant, however, that the great compendium which began to appear under Max Weber's direction and which was designed to replace a similar older work edited by Schönberg, was entitled *Grundriss der Sozialökonomik* (Tübingen 1914-) rather than *Handbuch der politischen Oekonomie*

(3 vols., Tübingen 1882-85). By their origin and also by the meaning of the single words of which they were compounded, the old terms pointed to a political and national emphasis; the new name in its colorless generality seemed exactly right for the new "objective" science, divorced from all judgments of value.

At about the same time theoretical interest was reawakened and theoretical work resumed. While the historical school was at its zenith the rationalistic and pure theory trends had not developed. Only a few scholars such as Lexis, Dietzel, A. Wagner, Neumann, Diehl continued in this period to build on the basis of the classical and the German theory; the new marginal utility doctrine of the Austrian school had exercised no substantial influence for an entire generation. But now the Anglo-American and the Austrian schools came to the fore in Germany (Schumpeter, Lederer) and theory was being developed even by adherents of the historical school (Spiethoff, Sombart, Alfred Weber, Plenge). Important contributions to theory were also made by the individualistic-liberal and individualistic-socialist groups (Liefmann, Oppenheimer), by Marxist revisionists (Lederer, Heilmann) and by the new universalistic school (von Gottl-Ottlilienfeld, Spann).

The rise of sociology in Germany also falls within this period. Of course the nineteenth century did not lack men of great sociological penetration. Nietzsche and Jakob Burckhardt, Ranke and Droysen, Schmoller and Gothein, intellectual leaders and scientific lights of varying brilliancy, often had a more profound sociological grasp of such large entities as peoples, epochs and cultures than professional sociologists attain in a lifetime of work. But a distinct science of sociology was not developed at that time. The works of Auguste Comte and Herbert Spencer had only slight influence; Lorenz von Stein's attempt at a doctrine of society foundered in contradictions from history; Ferdinand Tönnies' work of genius, *Gemeinschaft und Gesellschaft* (Leipzig 1887), in which he boldly created the fundamental concepts of German sociology, was not appreciated for twenty years. With the turn of the century the sociological work of philosophers and economists laid the foundation for the new science in Germany. Simmel's sociology and the work of Max Scheler showed how much sociological insight was to be gained from psychological observation and phenomenological explanation; the writings of Max Weber and Sombart, Alfred Weber and Oppenheimer,

showed with what subtle sociological sense leading economists interpreted the problems of the establishment and operation in society of the various cultural phenomena. A "formal" or "materialistic" sociology developed alongside of this more philosophical sociology. Methodologically akin to American researches, the new discipline of social relations (von Wiese) scrutinized many social formations in order to discover the underlying principles of association. Anthropology was also influenced by the new sociological trend, and the excellent work of the nineteenth century in primitive organization (Bachofen) was continued and supplemented by studies of primitive peoples and cultures (P. W. Schmidt, Thurnwald, Graebner).

The rapid increase in the subject matter of social science seemed to doom the old university practise which required every lecturer to treat all branches of social science or at least to be capable of doing so. Indeed, Max Weber declared separation into special disciplines essential, practically inevitable, and was certain that future developments would make the German university resemble the American institution. The rich variety of contemporary German social science can be properly understood only if it be borne in mind that Max Weber's prophecy was not fulfilled. Although the pressure of various mutually opposed trends resulted in a loosening up of the old academic scheme, it did not bring about specialized separation of all disciplines and chairs. It is significant that only a few German universities have professorships in sociology—Tönnies was *Privatdocent* up to his fifty-fourth year; Max Weber did his sociological writing when illness caused him to retire; Alfred Weber gave his sociological lectures as ordinary professor of political economy. The same condition prevails in other fields. During the last twenty-five years problems of the manufacture of credit (Schumpeter, Hahn) and business conjuncture and crises (Spiethoff, Lederer, Löwe) have been subjects of intensive investigations; but no special professorships for currency and credit or for business cycles were founded. Of the group of older disciplines only public finance showed a strong, widely recognized tendency toward separation in teaching and teachers. Of the newer subjects international economics, which is still associated chiefly with the person of Bernhard Harms, has attained the dignity of a separate discipline; so also has the economics of private business enterprise with all its subdivisions. Because the

latter had been developed as a special subject at the new higher schools of commerce, it was continued as a special subject when the schools at Frankfurt and Cologne were converted into universities.

Although the recent expansion of the social sciences has not resulted in a pronounced specialization, it has separated them more distinctly from the related disciplines of philosophy and history, and has emphasized their practical applications. In many cases the teaching of the social sciences was transferred from the faculty of philosophy to the law faculty; this is in line also with the general tendency toward an ever closer association of law and social science in education for public life. In other cases social-scientific instruction was entrusted to newly organized faculties of law and political science and, in less frequent instances, to special economic and social science faculties. A great deal of social science, particularly of applied and business economics, is being taught at present in the higher schools of commerce. Their number has increased considerably and their teaching program made broader so that the best of them differ little from the economic faculties of the newer universities. Owing to the traditional freedom of teaching and to the immunity from removal that professors enjoy as state officials, the question of the identification of the social science disciplines with a particular faculty is merely a matter of formal university organization. Its significance is limited to exposing the faculty members to a particular type of intellectual contact, and to the influence it may exercise on the choice of supplementary subjects by the students. It may explain, for instance, the relative neglect of philosophical and methodological disciplines by present day students who major in social science.

Another indication of the tendency to separate and to standardize the instruction in social science is the establishment in 1923 of a uniform examination in all federated German states for the diploma of *Volkswirt*. The significance of such a measure will appear more clearly if it is realized that the German student enjoys complete freedom in the choice of courses and in the sequence in which he attends them. The object of the new examination is to make more uniform, purposeful and intensive the course of study followed by the average student. The examination, taken after the completion of six semesters of social science, is both written and oral. The written part consists of an essay on an assigned

subject, prepared within a period of six weeks, and of two examination papers, one on an economic and the other on a legal topic. The oral examination covers general and special economics, public finance, statistics, business administration (for which may be substituted economic history or economic geography or the law of industrial relations), elements of civil and commercial law, general political science, and constitutional and administrative law. When a student passes the examination he becomes a candidate for the degree of *Doctor rerum politicarum* (or *Dr. oec. pub.* at Munich). This is awarded after the completion of two additional semesters of social science work, the presentation of a rather extended piece of independent scientific research and the passing of an examination covering the four principal subdivisions of economics and jurisprudence.

Since the establishment of the new degree, the doctorate in philosophy, which used to be frequent before, is now awarded only by a few outstanding universities (such as Berlin and Heidelberg) and only to those who specialize in the more theoretical phases of social science. The dissertation presented for this degree must deal with either economic or sociological theory and the examination covers theoretical and applied economics, sociology, and two supplementary subjects taught in the faculty of philosophy, generally philosophy and history. As a result the course of study of a candidate for the doctorate of philosophy is also somewhat different: he does not display as a rule an interest in business economics or practical law, but attends instead many more lectures on philosophical and historical subjects.

A tendency toward the democratization of faculties and the stimulation of research by financial assistance may be discerned in another post-war change affecting the teaching personnel. The teachers in German universities are divided into several groups: there are the ordinary or full professors, who give the large lecture courses basic for the faculty in question; lower in rank are the extraordinary professors, who may or may not be full-fledged faculty members; finally there are the *Privatdozenten* (private lecturers) and private persons engaged for special courses. The rank of *Privatdocent*, which is the first step in the academic ladder, is open to any university graduate who qualifies on the basis of a published book and of a special oral examination given by the entire faculty. The compensation for his lectures is limited en-

tirely to students' fees. Even under ordinary conditions this arrangement provides little financial security; but during the inflation period it proved entirely unsatisfactory because it resulted in a one-sided selection of persons of wealth for academic work. To remedy this evil two measures were taken. In the first place fellowships were granted to a limited number of *Privatdozenten* to tide them over until they should receive a paid appointment. The second change was the provision for an increased number of paid positions for assistants in research and teaching. Although a paid assistant may teach as a *Privatdocent* in his own right, he is ordinarily either a research worker or less frequently an assistant instructor taking over the more elementary portions of his superior's work.

Paid assistantship is not the only link between research and teaching. In Germany, as in other continental countries, an overwhelming proportion of research in the social sciences is done in the universities or at least in association with them. Such a relationship is strengthened by the fact that successful and voluminous research work is a prime qualification for an academic career. In addition to the scholarly labors of individual professors, the seminars were in the pre-war period responsible for a large share of the research output. At present more importance attaches to institutes forming an integral part of the universities or at any rate affiliated with them. The institutes are for the most part permanent organizations with a managing director and paid assistants. All of them have more or less specifically defined fields of research, some specializing in problems restricted to a definite region. The Institut für Weltwirtschaft und Seeverkehr at the University of Kiel, the best organized of them all, has influenced the development of similar organizations. Institutes of some size exist at the universities of Berlin, Breslau, Cologne, Frankfurt, Hamburg, Heidelberg, Königsberg, Münster, etc., and also at the Nuremberg school of commerce. The Institut für Konjunkturforschung at Berlin is the only institute not affiliated with an institution of higher learning. It is a part of the central statistical bureau of Germany and is engaged in a scientific treatment of statistical materials in order to elicit results of both theoretical significance and practical value.

Research by scholars with academic standing is not entirely confined to universities and associated organizations. A great deal of historical research has been done through the academies

of sciences and similar institutions which exist in several German states; their work was more important for the social sciences before the appearance of special research institutes within university walls. Many local associations for the study of specific subjects or for the correlation of science with practise also stimulate research work. Finally the learned societies of national scope bring about greater coordination of the researches of individual scholars and provide a publishing outlet for its results.

The Verein für Sozialpolitik is perhaps the oldest and most important of the learned societies in the field of social science. It was founded in 1872 in order to effect a wider acceptance of "socialism of the chair" in both theory and practise. In 1881, after Bismarck had definitely fixed the trend of the government's social policy, the society discontinued its attempts to influence general public opinion and sought instead to provide a basis for scientific discussion through extensive research. The meetings of the society, first annual and later biennial, provided the forum for an interchange of scholarly opinion. Gustav Schmoller, one of its founders and its president from 1890 until his death in 1917, decisively influenced the viewpoint of the society for nearly half a century. Under his successor, Heinrich Herkner, an increased interest in theoretical and financial questions led to the establishment of a separate subcommittee to deal with them. The society publishes a series of *Schriften* (175 vols. have appeared since 1879), which contain reports of proceedings as well as the results of research of the individual members. Although discussions of practical social and economic questions predominate in this collection, its range is really much wider than problems of German social policy. Alongside of studies on farm labor and handicrafts in Germany, one finds articles on the commercial policy of the principal countries, on French and American trade unions, on German financial and monetary problems and on international cartels.

A learned society whose prominence is of more recent date is the Deutsche Gesellschaft für Soziologie, established in 1909 and honored by the presidency of Tönnies. Its membership is limited to persons with a well-established interest in sociology. It is of service to science mainly through its conventions, in which all schools of thought are represented and the proceedings of which are published in full. The discussions in these conventions range over a wide variety of problems, taken from the formal

as well as empirical, psychological as well as cultural, branches of sociology. Side by side with topics like the relation of technology to culture or of law to economic life, the conventions discuss the sociological significance of nationality and of revolution, or the metasociological question of understanding. Since 1926 special groups have met in addition to the general convention. They consist of professional scholars and deal with a limited branch of sociology, such as the methodology of the social sciences (Sombart), anthropological sociology (Thurnwald) and the science of social relations (von Wiese).

The Friedrich List Gesellschaft is more than a learned society. Established in 1925 and directed by its president, Bernhard Harms, it seeks to bring about a collaboration of scholars and men of affairs in order to furnish carefully thought out solutions of current economic and social problems. Its task in the publishing field is to arrange for a complete and authoritative edition of the works of Friedrich List and to stimulate interest in the history of the social sciences by the publication of numerous series of studies. So far two volumes of the List edition have appeared; the proceedings of two important conventions, *Deutsche Verkehrsprobleme der Gegenwart* and *Das Reparationsproblem*, have also been published.

It will be observed that none of the series of studies described above represents the product of a definitely articulated school of thought. With the single exception of *Deutsche Beiträge zur Wirtschafts- und Gesellschaftslehre*, founded by Othmar Spann and Georg von Below and having a pronounced universalist viewpoint, contemporary Germany does not possess a publication which serves as the center for a recognized school or tradition. These series of studies, if they are more than compilations for convenience in publishing, are as a rule characterized more by external limitations than by adherence to a definite viewpoint. The series of dissertations published by some universities (Munich, Jena, Greifswald, etc.) or by a combination of several universities (Badische Hochschulen), or the *Sozialwissenschaftliche Forschungen*, a series of the best dissertations prepared at any German university, display obviously a wide variety of viewpoints. Some series confine themselves to dissertations prepared under a single professor; these of course are bound to possess a greater uniformity of outlook. Of such character was the old *Staats- und sozialwissenschaftliche Forschungen*, edited by Schmoller and affiliated

definitely with the younger historical school. Another rather external limitation which may characterize a series is that of the range of subjects treated. Of this type are the *Probleme der Weltwirtschaft*, edited by Harms, and *Finanzwissenschaftliche und volkswirtschaftliche Studien* founded by Karl Bräuer for a serious discussion of public finance in post-war Germany.

The observations made about these series of studies are equally applicable to present day social science periodicals in Germany. The contrast with the situation in the nineteenth century is well marked. Although functioning under flexible limitations as to the branch of sciences which it attempts to serve, a modern German periodical welcomes as a matter of principle scientific contributions of all schools and methodological orientations. Nevertheless a keen observer would still detect certain characteristic differences. For instance, *Schmollers Jahrbuch für Gesetzgebung, Verwaltung und Volkswirtschaft im deutschen Reiche* (est. 1877 as quarterly, ed. by Schmoller 1881-1917, bimonthly since 1925, present editor A. Spiethoff), once the leading organ of the younger historical school, still remains the recognized center of publication for all research in the field of historical and empirical theory of economics and politics. Likewise the *Archiv für Sozialwissenschaft und Sozialpolitik* (bimonthly, est. 1904, present editor Emil Lederer), once edited by Max Weber and Werner Sombart in the spirit of "emancipation from value judgements," is distinguished today by habitual recurrence of rationalistic-theoretical, sociological and socialistic studies. Yet these distinctions are neither fundamental nor permanent. It is significant that editors of one periodical regularly contribute to other rival periodicals, a situation scarcely conceivable before the war.

In addition to *Schmollers Jahrbuch* and the *Archiv*, one must note the *Zeitschrift für die gesamte Staatswissenschaft* (bimonthly since 1926, est. 1844 by Robert von Mohl, numbering among its editors Schäffle, Schönberg, A. Wagner and Karl Bücher; present editor Georg Brodnitz), equally wide in scope, embracing all branches of social science. Somewhat more limited to economics with an emphasis on its practical and statistical aspects are Conrad's *Jahrbücher für Nationalökonomie und Statistik* (monthly, est. by Bruno Hildebrand, ed. 1872-1915 by Johannes Conrad, present editor Ludwig Elster), and the *Weltwirtschaftliches Archiv* (quarterly, est. 1913), organ of the Institut für

Weltwirtschaft und Seeverkehr and edited by Harms. The *Vierteljahrschrift für Sozial- und Wirtschaftsgeschichte* (est. 1903 by St. Bauer, G. von Below and L. M. Hartmann, the first of whom is still editing it) is the outstanding German periodical in the field of economic history. *Finanz-Archiv* edited since its establishment in 1884 by Georg Schanz, is a semi-annual periodical of international reputation, cultivating a special branch of economics. There has been a large recent growth of periodicals devoted to the new science of business economics and management. The outstanding ones are *Annalen der Betriebswirtschaft* (quarterly, est. 1927, ed. by A. Heber), *Zeitschrift für Betriebswirtschaft* (monthly, est. 1924, ed. by F. Schmidt) and the older *Zeitschrift für handelswissenschaftliche Forschung* (monthly, est. 1906, ed. by K. Schmaltz). The *Allgemeines statistisches Archiv* (quarterly, est. 1890 by Georg von Mayr, ed. by Friedrich Zahn) is the leading periodical dealing with general statistical problems. Political science in its theoretical and empirical aspects is stimulated by articles in the *Archiv des öffentlichen Rechts* (quarterly, est. by Paul Laband, ed. by G. Holstein, O. Koellreutter and H. Triepel) and in the *Vierteljahrschrift für Politik und Geschichte* (est. 1923 as *Archiv für Politik und Geschichte*, ed. by Hans Roeseler). The important sociological magazines are *Kölner Vierteljahrshefte für Soziologie* (est. 1921; L. von Wiese is one of its editors), *Zeitschrift für Völkerpsychologie und Soziologie* (quarterly, est. 1925, ed. by R. Thurnwald) and *Ethos* (quarterly, est. 1925, ed. by D. Koigen, F. Hilker and F. Schneersohn). The socialist periodicals *Sozialistische Monatshefte* (monthly, est. 1896, ed. by Joseph Bloch) and *Die Gesellschaft* (monthly, est. 1924, ed. by Rudolf Hilferding) often contain scholarly articles on various social-scientific problems. Finally it must be mentioned that many research institutes publish periodical bulletins and that serious studies can often be found in the more specialized periodicals dealing with practical problems of business, public finance, trade unionism and cooperation.

In summing up we may observe that neither as teaching disciplines nor as research programs do the social sciences in contemporary Germany display uniformity of viewpoint or of method. A new synthesis of theory, history and practical studies is sought on every hand, but there has not developed a dominant tradition nor has a generally acknowledged leader appeared. Under the old faculty designations and in the new re-

search institutes, through societies and periodicals, each new trend develops its own doctrines and hopes to bring about their general acceptance.

IV

Austria and Hungary

I. AUSTRIA. This section refers only to the territories comprised in the present Austrian Republic. In most of the other regions of the former empire the social sciences have developed not only in a foreign language but in a fundamentally divergent spiritual environment as well.

Austrian and German social science research have always been associated in the closest kind of interrelationship. Most of what can be said about the social sciences in Germany is applicable to Austria as well: the ethnic and linguistic kinship has proved distinctly a stronger influence than the political separation. To avoid repetition we shall in this section place the emphasis on those viewpoints in which Austrian social science research diverges from the general German stream, and thereby reveals distinctive Austrian traits.

The contrast between south German Catholicism and north German Protestantism, and the fact of Austria's political separation, have always been the two most important causes of occasional divergences between Austrian and German social science currents. The political mission of the former Austrian Empire was to unite in a state a multiplicity of historically and nationally quite heterogeneous peoples: this endeavor emerges consistently in Austrian social scientific thought. We can perhaps observe it most clearly in the social science echo of the romantic movement. The German romantic movement, which lifted German culture out of the general stream of the European Enlightenment, directed the social sciences toward an essentially idealistic and, beyond that, a nationally conditioned historical viewpoint, while in Austria it evoked social science theories that were partially rationalistic in motivation and absolutist and centralizing in tendency.

In the practical execution of her centralistic political aspirations Vienna could not afford to stress too strongly either the historic or the juristic point of view, for she had to curb a multiplicity of nationalities which stood on the soil of their own rich historic and juristic traditions. The political union of the Austrian

peoples seemed firmly grounded only on the plane of economic unity. So the former Viennese government missed no opportunity of bringing out the idea of reciprocal economic advantages and of planting it deep in the consciousness of its subjects. Small wonder, therefore, that economics became the central point of Austrian social science research at a comparatively early date. Moreover we find here the reason why economics as a subject of instruction has from the beginning belonged to the law and political science faculty of Austrian universities.

The development of Austrian economics and finance down to the present day reveals three flourishing periods quite clearly. In the first period the political viewpoint in its distinctively Austrian character played a leading role. When in the second half of the seventeenth century mercantilistic ideas began to penetrate into German speaking areas, an active group of nationalist economic writers was formed about the Viennese court, which brought out very sharply the fundamental idea of all mercantilism, the economic emphasis on the absolute monarchy. In the history of thought these writers are called the south German Catholic branch of the cameralists. Generally speaking, neither physiocracy nor the individualistic liberalism of the classical school succeeded in fruitfully stimulating Austrian economic thought, for the liberal current was in direct opposition to the Hapsburg state. So much the more would conservative and interventionist viewpoints in economic research necessarily flourish in the Viennese environment. The absolutism of the Holy Alliance greeted them with open arms. It is, however, decidedly significant that the historical school itself, which after all sprang from romantic thought, received comparatively little attention in Austria. Researches in economic history were likely to remind the different peoples of the monarchy of their former political independence. It was necessary to turn their attention in exactly the opposite direction toward the present and the future, toward the economic advantages to be expected from their political union by reason of a

division of labor and mutual aid. The rationalistic, thoroughly abstract, deductive system of thought which brought forth the theory of marginal utility was admirably adapted to this purpose, and that explains why it could flourish so exuberantly in Austria.

Perhaps the two decades before the World War, when the Austrian marginal utility school stood at the height of its power, are at the same time to be looked upon as the Golden Age of Austrian social science research. Not only did the Austrian marginal utility theory celebrate a triumphal progress geographically over extended foreign territories; it pushed forward into neighboring regions of thought as well, and inspired the hope that the struggle over method which it involved would raise economics to uncontested leadership among all the social sciences.

With the breakup of the Austrian Empire after the World War, the efforts of the earlier, characteristically Austrian research to support it theoretically likewise disappeared. At first German nationalism raised its head, and forces hitherto suppressed were developed in a thoroughly organic, speculative economy. This fresh new current is called universalism. It delves consciously into the organic thought treasure of former times, but especially into the economic doctrines of the romanticists, and stands in sharp opposition to the individualistic traditions of the marginal utility school. The present status of Austrian economic research is characterized by this struggle.

Sociology in Austria has always developed in the wake of economics; economic changes are mirrored rather consistently in Austrian sociological thought. West European influences predominated to about the time of the World War; the individualistic and partially mechanistic trend of the marginal utility theory was favorable to the positivistic and rationalistic doctrines of sociology. Since the World War new currents have appeared in two directions. In the first place the reaction against the marginal utility school emerges in the realm of sociology with a purely conceptual universalist system of thought which is recognized even beyond the boundaries of Austria. No less important is the second current which emanates from the philosophy of law and develops the principles of sociology on the basis of neo-Kantian ideas.

As in economics, so in the science of law and in other political sciences Austrian development has been closely bound up with the

centralizing aspirations of the Viennese government. The intention of bringing, so far as possible, the various peoples of the monarchy closer together by means of a uniform system of law led to early codification which played a significant part not only within the monarchy, but also within the whole domain of German law. Hence it is that in Austrian juristic research the dogmatic viewpoints of positive law have been strongly predominant since the beginning of the last century. After the World War neo-Kantian law philosophy took a sudden rise in Austria—we have just referred to it in connection with sociological research. The effort was made to grasp the essence of the law concept on purely idealistic grounds, and thus to establish its connection with positive law, the function of which consists only in determining content.

During the period of imperial government Austrian statistical research enjoyed a very favorable environment. As early as the seventeenth century the Viennese government sought to facilitate its centralistic activity by statistical compilations. So in the eighteenth century it enjoyed the prestige of having for the first time carried through a general census for a large country at one and the same time and with one and the same viewpoint. In 1829 an administrative statistical service was organized in Vienna. In 1863 it was enlarged into a central statistical commission, which since 1921 has continued its very active work as a national statistical office. The activities of this office have made possible the various branches of statistics that have flourished in Austria. There are, in addition to figures dealing with population and nationalities, several kinds of statistics bearing on administrative and economic problems. Statistical research at the universities has always been in closest relationship with official statistical work. Courses in statistics were given at all Austrian universities as far back as the beginning of the last century.

Of any distinctively Austrian historical research it would be difficult to speak in a methodological sense; interrelations with German science are so strongly developed here. In general special features are the result only of objective specialization on cycles of problems which are particularly important in Austrian history. Thus the question of nationalities has always received much attention. The series of events in the rise of the house of Hapsburg have also been always in the foreground. In a measure the pan-

Germanic idea emerged rather sharply. Research and critique of mediaeval archives flourished at the University of Vienna beginning with the end of last century. Perhaps, however, Austrian historical research has matured its most valuable fruits in the domain of economic history—another proof of the central position of economics in the framework of Austrian social science. Austrian intellectual history has also had several notable triumphs to record recently.

Some of the marginal social science disciplines succeeded in taking root in Austria with most favorable results. The wealth of the Hapsburgs permitted the flourishing of the imperial museum collections and therewith of archaeology, while aesthetic research has been stimulated by the general love of art in Vienna. The ethnic and linguistic heterogeneity of the former monarchy presented an admirable foundation for philological study and, in partial connection with it, for ethnology and anthropology also. Moreover anthropology has been materially promoted by the advanced medical science of Austria; Austrian biological and psychological researches in their social bearings owe their development in part to this source.

The University of Vienna must be regarded as the center for all these social disciplines in Austria. Founded in 1365, it is the second oldest university in Central Europe. The centralistic politics of the imperial court and of the former Viennese government redounded particularly to its benefit; in this way the social sciences could develop favorably there too. Amply provided with appropriate chairs of learning, with seminars and special research institutes, the University of Vienna has always had a strong attraction for foreign as well as native students. Contemporary Austria is trying by every means to maintain the high level of the University of Vienna, for it is conscious of the fact that Vienna's former political power can be replaced in the cultural sphere only in this way. As centers of instruction in the social sciences, the universities founded at Graz in 1585 and at Innsbruck in 1673 must also be taken into account. Of significance for German speaking Austria from this point of view must be reckoned the University of Prague, founded in 1348, the oldest university in central Europe, and the University of Czernowitz, founded in 1875. After the World War these two universities were ceded to Czechoslovakia and Rumania respectively. An attempt was made at

that time to introduce, in addition to the traditionally united law and political science faculty, special political science instruction after the German model, but the effort met with little success.

There are, in addition to the university in Vienna, a number of important advanced schools of equivalent rank, in which not only economic subjects are taught but individual legal and political disciplines as well. Worthy of note from this point of view are the Export-Akademie, founded in 1898, transformed in 1919 into a Hochschule für Welthandel; the Hochschule für Bodenkultur (1872); the Konsularakademie (1754), an advanced public school since 1919; also the Wiener Technische Hochschule. Popular university courses and lectures, given outside the universities and advanced schools, are highly developed in Austria. With the vigorous cooperation of university professors and advanced school teachers they render useful service in the spread of knowledge in the social sciences. The Wiener Internationale Hochschulkurse, annually organized every fall since 1922, has served the same purpose internationally. Generally speaking, Austria endeavors rather to bring foreign students into the country than to send her own students into foreign countries. Consequently Austrian students of the social sciences are for the most part dependent on fellowships and subventions of foreign foundations.

In addition to the ranking and comparatively well-equipped seminars and research institutes of the University of Vienna in economics, sociology, jurisprudence, history, statistics and other social sciences, there are, besides, of some importance: the Oesterreichisches Archäologisches Institut (1898), the Oesterreichisches Institut für Konjunkturforschung (1927), the Forschungsinstitut für Gemeinwirtschaft affiliated with the Gesellschafts- und Wirtschaftsmuseum, the Forschungsinstitut für Osten und Orient (1916), the Wissenschaftliches Institut für Kultur und Geschichte des Sudetendeutschums (1920), the Institut für Genealogie, Familienrecht und Wappenkunde (1922) and the Forschungsinstitut für Rassen- und Konstitutionsanthropologie, affiliated with the Naturhistorisches Staatsmuseum (1923).

Of the Vienna museums the following are important from the standpoint of economic science: the Oesterreichisches Museum für Kunst und Industrie (1863), the Technisches Museum für Industrie und Gewerbe (1918) and the

Technologisches Gewerbemuseum (an institution for instruction and experiment); for historical research the Historisches Museum der Stadt Wien (1888), the Kunsthistorisches Museum (1891) and the Oesterreichisches Heeresmuseum (1885) are to be noted; for ethnology and anthropology the corresponding divisions of the Naturhistorisches Museum and the Museum für Volkskunde (1896).

Like the museums the Vienna libraries derived benefit from the centralistic endeavors of the earlier governments and from the wealth of the imperial dynasty. The Hofbibliothek (called Nationalbibliothek since 1920), founded in the second half of the sixteenth century, is one of the most important in Europe so far as the social sciences are concerned. In addition to the university and advanced school libraries, and the libraries of the federal chancellery and of various ministries, special reference must be made to the Wiener Stadtbibliothek (1856), the Bibliothek des Bundesamtes für Statistik and the Bibliothek des Nationalrates (1870). Of the Vienna archives these are especially valuable: the Haus-, Hof- und Staatsarchiv (1749), the Hofkammerarchiv (1516), the Archiv der Stadt Wien, the Kriegsarchiv and the Deutschordens-Zentralarchiv (1904).

Since the University of Vienna, with extremely extensive interests, covers a very material portion of the work in Austrian social science, and since the German social science societies and associations extend their keen activity to Austria as well, the sphere of the corresponding Austrian associations is comparatively limited. The most distinguished among them is the Wiener Akademie der Wissenschaften (1847), which materially advances the social sciences through the numerous special commissions of its second division. For economics only, the Oesterreichische Gesellschaft für Sozialpolitik (1924) is to be taken into account. The erstwhile very active society of Oesterreichische Volkswirte was already discontinued during the World War. For historical science these societies are important: Verein für Geschichte der Stadt Wien (1853), with its yearbooks; the Gesellschaft für die Geschichte des Protestantismus in Oesterreich (1879), likewise with its yearbooks; the Heraldische Gesellschaft "Adler" (1870), with its monthly journal, and the Wiener Prähistorische Gesellschaft (1914), with the *Wiener prähistorische Zeitschrift*. Dedicated to jurisprudence are the Wiener Juristische Gesellschaft (1867), the

Oesterreichische Kriminalistische Vereinigung (1906) and partly also the Internationaler Anwalt-Verband (1899), with its periodical *Gerichtshalle*. For anthropology and ethnology reference must be made to the Anthropologische Gesellschaft (1870), with its *Mitteilungen*, and to the Verein für Volkskunde (1894), with the *Zeitschrift für Oesterreichische Volkskunde*, and to the Oesterreichischer Heimatschutzverband (1913), to which belong all Austrian associations for the preservation of national customs and folklore. The Geographische Gesellschaft, which publishes *Mitteilungen*, was founded as far back as the year 1856. Finally in the fields of philology and psychology the following are to be noted: the Wiener Neuphilologischer Verein (1894); the Internationaler Verein für Individualpsychologie (1911), with the *Internationale Zeitschrift für Individualpsychologie*; the Wiener Psychoanalytische Vereinigung (1922), with the *Internationale Zeitschrift für Psychoanalyse*, and the Internationale Religionspsychologische Gesellschaft, with the *Archiv für Religionspsychologische Forschung*. Devoted only partially to the pursuit of the social sciences in general are the Oesterreichische Leogesellschaft (1892), with its yearbooks, and the Wissenschaftlicher Klub in Wien (1876), with its monthly journal.

Despite the multiplicity of separate Austrian social science societies and periodicals, the center of gravity of Austrian achievement in this field lies in the work which is performed jointly with German social science research. Austrian social scientists are constantly working for German periodicals and occasionally even editing them. The same interchange takes place in connection with joint compilations and textbooks. Exchange students and professors have always been most numerous between Austrian and German universities. As a result of this extremely active interrelation, which we must again emphasize in conclusion, it is often quite difficult to draw a dividing line between Austrian and German social science research. It should be added that there is in Austria no desire to stress such a boundary. For the movement toward union with Germany strongly asserts itself in the field of the social sciences.

II. HUNGARY. The Hungarians are a nation of jurists. One of the most prominent traits in their character is the lively interest, among the most widely separated strata of society, in problems of public law. The high development of this interest is due to the peculiar history of their

country. Surrounded by peoples ethnically foreign, the Hungarian state could maintain itself during the thousand years of its existence only by constant political struggles. This is the first reason why problems of public law have always been in the foreground. A second reason may be found in the eternally problematic political relationship to the other half of the former Austro-Hungarian monarchy. Finally, since the breakup of the monarchy, the aspiration toward a revision of the Treaty of Versailles has been strongly influenced by a public law viewpoint.

This general preoccupation brought with it, as the earliest development in the field of the social sciences in Hungary, the juristic and political disciplines, which still maintain their lead today. Juridical subjects were expounded in the oldest Hungarian universities—in the university at Pécs, founded in 1367, and in the universities at Óbuda and Pozsony which date, respectively, from the end of the fourteenth and the middle of the fifteenth centuries. But while these early universities did not survive, a leading role should still be assigned to the juristic faculty established in 1667 at the University of Nagyszombat, which later moved to Budapest. At first this faculty consisted of only four chairs of instruction, dedicated respectively to Roman law, canon law, Hungarian positive and formal law. A differentiation in these branches of instruction, and the addition of other juristic and political subjects, followed in the course of later centuries. In addition to these faculties at the University of Budapest complete faculties of law and political science exist now in the universities at Szeged and Debreczen and in the new university at Pécs. Significant as showing the extent of Hungarian juristic and political instruction is the fact that there were in addition twelve law and political science schools called law academies, whose curricula corresponded with those of the universities. Only three of these independent schools still exist—in Miskolc, Eger and Kecskemét.

The law of custom plays an extremely important part in Hungary even today. Moreover the Hungarian constitution is decidedly historical in character. Hence the historical viewpoint has long been prominent in Hungarian juristic research and in the always closely associated research in political science. It was only during the second half of the last century, when codification of laws was making great strides, that a new energy manifested itself in

the institution of positively directed research. In addition, attempts to codify Hungarian civil law, which had been going on for decades, served to bring out strongly the legalistic, political viewpoint. After the important pre-war literary creations, embracing whole fields of knowledge, especially private law, commercial and criminal law, procedure and state and administrative law, this last decade, juristically and politically so restive, has yielded mainly monographic treatments.

History as a discipline developed mainly within the faculty of philosophy of the University of Nagyszombat during the eighteenth century. Instruction in history was introduced also into other philosophic faculties and was later partially included in the law faculties as well. In general, public law and also statistical and geographical influences played an important part in historical research in Hungary as far back as the beginning of the eighteenth century. Protestant scholars were leaders in this research; while Catholic investigators—especially Jesuits—applied themselves mainly to studies in church history. In the second half of the eighteenth century the two currents were combined in active, critically conducted, historical research. Later, however, during the romantic period the scholarship preoccupied with original sources suffered a certain decline. Only since the second half of the last century has it flourished again by dint of modern methods and a far reaching, systematic division of labor. In the last generation the juristic, economic and socio-historic viewpoints have again been emphasized. Since the dismemberment of the country, Hungarian historical research still looks upon the lost territories as within the field of its labors.

Economics has been included in the curriculum of the law faculties since the beginning of the last century. Recently, in 1914, instruction in economics was materially extended by the establishment of an economics faculty at the Budapest Higher Technical School. In addition, several older, independent schools, with economic interests and university rank, have been combined to make possible a special University Faculty for Economics in Budapest, with twenty-two chairs of instruction and well-equipped seminars. Everywhere in Hungary instruction in finance is closely connected with the course in economics. After an initial inclination to classical economic theory of individualistic-liberal stamp, Hungarian research in eco-

nomics produced its first internationally distinguished fruits in the second half of the last century, under the influence of the German historical school. A socio-ethical current made itself felt particularly strongly about this time. The psychological and mathematical viewpoints of modern abstract theory found much favor during the last decades of the century. But gradually the significant public law viewpoint, so characteristic of the Hungarian way of thought, also penetrated into economic research; and just recently the juristic presuppositions of economic institutions have been emphasized by Hungarian writers with ever growing success. In addition, the general political interest of the Hungarian has brought forth several noteworthy scientific achievements in the field of social politics and economic policy.

The teaching of statistics in Hungary is confined to the law faculties. The development of this science was for a long time held back by unfavorable political conditions, but, since the second half of the last century—that is, since the founding of the National Statistical Bureau (1871) and of the Statistical Bureau of the City of Budapest, both decidedly of first rank—it has made a sharp ascent. It changed rapidly at that time from a mere description of the notable events in the life of the state to modern, methodical observation of the conformities that emerge in the social growth. Scientific achievements in Hungarian statistics are characterized by profound methodological observation and by a lively socio-ethical sense. Hungarian research may claim great significance in the field of enterprise and business statistics, in the perfection of export statistics on the basis of international cooperation, and in individual branches of public health statistics.

The prominence given to public law in Hungarian thought and the central position of juristic and political science, as the two decisive emphases in the development of all the social disciplines, manifest themselves most clearly in Hungarian sociological research. As a result of this lively interest in public law Hungarian sociology, just as it was attaining a higher development at the turn of the century, was drawn into the proscribed area of political struggle. This fact explains why it has been impossible, even to this day, to establish separate chairs of sociology in the Hungarian universities. Sociological lectures are held only here and there. As to content, the predominant role of juristic and political science appears

especially in this: that sociological research in Hungary received its most valuable stimulus from juristic philosophy; it received, besides, most inspiring contributions from general political science. On the soil of these two influences it has developed a fruitful, idealistic attitude in speculation, which partially inclines toward the Kantian theory of norms. The second main current of Hungarian sociological research bears the impress of Comtian positivism, of Darwinian materialistic evolutionism and of the Spencerian organic theory. Adherents of this phase of sociological theory became extremely active during the decades before the World War.

In the second half of last century the Finno-Ugric extraction of the Hungarian people was established, as against the Turko-Tartar hypothesis, in the course of a long controversy which brought about the rise of comparative philology in Hungary. Ethnology and anthropology both gained strength from the controversy. As to the socially important philosophical sciences, it is to be noted that a chair of aesthetics had already been established in 1774 at the University of Nagyszombat. Hungarian pedagogical research is also of comparatively early origin; indeed Comenius worked in Hungary for several years about the middle of the seventeenth century. Recently the socio-pedagogical and in a measure also the psycho-technical trend of modern pedagogy has excited special interest. Ethical research, in its socio-ethical relations, has always rendered most useful service to the Hungarian social sciences. The disciplines mentioned in this paragraph are taught in the faculties of philosophy in the universities.

The Hungarian Scientific Academy deserves a most conspicuous place in the history of the development of the social sciences in Hungary. Founded in 1825, it has since assembled, especially in its second division, the most distinguished Hungarian representatives of the social sciences. Its activity concerns especially the organization of lectures and discussions, the publication of historical and other source material, of scientific compilations and individual monographs, and the publication and subvention of scientific periodicals. Most of the social disciplines in Hungary owe their present degree of development mainly to the stimulation received from the academy. By reason of large gifts the academy has recently come into a position where it will be able to extend its activity even more widely in the future.

In addition to chairs for the separate social disciplines, all Hungarian universities have arranged seminars after the German pattern in which the students approach a practical understanding of what they have learned under the leadership of the professors and their assistants. Social science research institutes outside the universities are only in process of formation. A Sociographic Institute was established in Budapest in 1924 for the observation of general social phenomena. The Socio-Political Institute in Ujpest (1910) seeks to investigate living conditions among factory workers, while the Hungarian Institute for Economic Research in Budapest is dedicated mainly to the observation of the business cycle. Since approximately the beginning of the century popular university courses, in which the social sciences occupy front ranks, have been held in Budapest and several other Hungarian cities. In general, however, these courses drew a comparatively poor attendance. After the war an unsuccessful attempt was made to introduce into intermediate school instruction the principles of economics and of sociology in addition to history. Great significance attaches to the Hungarian Historical Institutes, founded in Rome and Vienna in 1888 and 1919 respectively, and active in gathering from the Vatican and the Vienna archives material that is valuable from a Hungarian standpoint. After the war Hungarian colleges were established in Berlin, in Vienna and in Rome. They offer numerous young Hungarian scholars the opportunity to penetrate into the spirit of foreign social science. Lately numerous fellowships for the same purpose have been granted annually, in part by the Hungarian government and in part by foreign scientific societies and foundations.

Besides the various divisions of the National Museum in Budapest, the following Hungarian museums are of especial significance for the individual social disciplines: the Social Museum, the Museum of Commerce, the Agricultural Museum, the Museum of Industrial Technology, the Museum of Military History, the Museum of Industrial Arts, the Museum of Plastic Arts, the Hopp Ferencz East Asiatic Museum and the Museum of Public Health, all in Budapest; also the Museum of Christian Art in Esztergom. The most important Hungarian library for the social sciences is the Municipal Library in Budapest; others, likewise important, are the Budapest libraries of the National Museum, the Scientific Academy,

the Parliament and the National Statistical Bureau, also the various advanced school libraries and, above all, the library of the University of Budapest. Among the archives these are especially to be noted: the great National Archives in Budapest, the archives of the Budapest National Museum, and those of the Prince Bishop of Esztergom. Valuable libraries and archives were lost in the dismemberment of the country. Since 1922 most of the public scientific collections of Hungary have been combined in a great country wide union, so as to secure the advantages of unified management.

Numerous Hungarian scientific societies are developing a very lively activity in the field of the social disciplines. Some of these societies strive toward a popularization of the social sciences. For jurisprudence front rank is held by the Hungarian Association of Jurists, founded in 1879, with its periodical, *Magyar Jogászegyleti Ertekézesek* (Transactions of the Hungarian Association of Jurists). In the domain of historical science the Hungarian Historical Association (1867) is especially worthy of consideration, with its periodical, *Századok* (Centuries); also the Hungarian Archaeological Society (1878), with the periodical, *Archaeologiai Ertesito* (Archaeological Reports); the Minerva Society (1921), with yearbooks and the periodical, *Minerva*; also the Hungarian Heraldic and Genealogical Association (1883), with the periodical, *Turul*. For political economy the Hungarian Society for Political Economy (1894) is to be noted, with its periodical, *Közgazdasági Szemle* (Review of Political Economy); for statistics the Hungarian Statistical Society (1922), with the French periodical, *Journal de la Société Hongroise de Statistique*; for sociology the Hungarian Social Science Society (1925), with its periodical, *Társadalomtudomány* (Social Science). The following periodicals are sociologically important: *Budapesti Szemle* (Budapest Review); *Városi Szemle* (Municipal Review); *Statisztikai Szemle* (Statistical Review); *Századunk* (Our Century); also the *Magyar Filozófiai Szemle* (Hungarian Philosophical Review), edited by the Hungarian Philosophical Society (1900). For pedagogy, aesthetics, linguistics, ethnology, anthropology and geography the following deserve prominence: the Hungarian Pedagogical Society (1876), with the periodical, *Magyar Paedagógia* (Hungarian Pedagogy); the Hungarian Society for Child Study and Practical Psychology (1903), with the periodical, *A Gyermekek* (The Child); the Association for

Higher School Teaching (1907), with the periodical, *A Felsőoktatásügyi Egyesület Közleményei* (Reports of the Association for Higher School Teaching); the National Hungarian Association for Plastic Art (1861) and the National Hungarian Association for Industrial Art (1885), with the periodical, *Magyar Imparművészet* (Hungarian Industrial Art); the Budapest Philological Society (1874), with the periodical, *Egyetemes Philologiai Közlöny* (General Philological Reports); the Hungarian Linguistic Society (1904), with its periodical, *Magyar Nyelv* (Hungarian Language); the Hungarian Ethnographic Society (1889), with its periodical, *Népélet* (Folk Life); the Turanic Society (1910) with its periodical, *Turán*; the Körösi Csoma Society (1920), with its periodical, *Keleti Szemle* (Eastern Review); and the Hungarian Geographic Society (1872), with the periodical, *Földrajzi Közlemények* (Geographic Reports). Societies which reach out into several fields of knowledge but which are also of special importance for the social sciences are the Saint Stephan Academy (1915), the Protestant Literary Society (1888), the Hungarian Society for Foreign Politics (1920), the Hungarian Scientific Society Urania (1899), the Budavár Scientific Society (1920); also the associations of the Friends of Szeged

(1922), of Debrecen (1922), and of Pécs Universities (1921). After the war the scientific societies of Hungary, like the public scientific collections, were combined in a great country-wide union.

In general these societies and their periodicals provide the connection between professional activity, under the leadership of university professors for the most part, and wider groups of the educated public. In addition to the periodicals mentioned other social science literature is enjoying a most gratifying growth. Even in the subdivisions of most of the sciences the students have had good Hungarian textbooks at their disposal for two or three generations. However, in view of the linguistic isolation of the country, some Hungarian writers consider it necessary to publish the results of their social science research, either entirely or at least in summary, in one of the world languages. German is generally preferred, inasmuch as the spiritual ties, even in respect to the social sciences, are strongest with Germany and Austria; indeed the most important literary influence has always come from these countries. Occasionally, however, French and English are used, even Italian in individual instances.

THEO SURÁNYI-UNGER

V

Italy

I. ITALY TO THE END OF THE WORLD WAR. The progress of the social sciences in Italy is bound up with university instruction. This is in accordance with the observations of John Stuart Mill regarding the development of a learned class. "The most effectual plan and at the same time the least liable to abuses," he wrote, "seems to be that of conferring Professorships, with duties of instruction attached to them. The occupation of teaching a branch of knowledge, at least in its higher departments, is a help rather than impediment to the systematic cultivation for original researches, and the greatest advances which have been made in the various sciences, both normal and physical, have originated with those who were public teachers of them; from Plato and Aristotle to the great names of the Scotch, French and German Universities."

The academic teaching of the social sciences in Italy dates from 1754, when Bartolomeo Intieri, a Tuscan abbot, founded a chair of political economy at the University of Naples. In the agreement with the university Intieri stipulated that instruction be given in Italian, a radical innovation at that time; that Antonio Genovesi occupy the chair for life; that Genovesi's successors be selected by competition; and that no occupant of the chair be chosen from the ranks of the regular clerics. It was also stipulated that instruction in mechanics and commerce was to cover a two year period.

At the time of his appointment to the new chair of political economy, Genovesi was forty years old. He had already been professor of philosophy, metaphysics and ethics, and only his somewhat unorthodox Biblical criticisms had prevented his being appointed professor of theology. Genovesi's enthusiasm for his new duties was shared by his students. Until his death (1769) he lectured to crowded audiences, which frequently included illustrious foreign scholars; and the impetus to the study of the social sciences in eighteenth century Italy was in large measure due to his eloquence and erudition. He discussed the works of John

Cary, Locke, Melon, Dutot, Forbonnais, Ustariz, Ulloa, Montesquieu and Hume. In 1765 he published his lectures on commerce and civil economics; they went through several editions in Italy, were translated into German in 1776, into Spanish in 1785, and remained in use as a textbook in Italy for many years. Although Genovesi was neither free from mercantilistic prejudices nor absolutely opposed to the regulation of internal commerce, he attacked privilege and monopoly, which led an adversary to declare that he was the first to arouse the democratic spirit. The most prominent representatives of Neapolitan erudition in the last decade of the eighteenth century were his disciples, and it was his teaching that inspired the works of Filangieri, Palmieri, Briganti, Pagano, Galanti, Delfico, Torcia and many others, all zealous promoters of the cause of scientific progress and of social betterment.

Cesare Beccaria's teaching, which began January 9, 1769, in the Palatine Schools of Milan, was less influential. Beccaria, famous as the author of *Dei delitti e delle pene*, taught what was known as cameral science, although it dealt with political economy, as may be observed from the lectures which circulated in manuscript and were published by Custodi in 1804, ten years after the author's death, in the collection of Italian economists. He relinquished his post after two years, for he was appointed to the Supremo Consiglio di Economia in 1771. Both Beccaria and Verri were instrumental in doing away with the guilds and also in instituting other reforms in the economic and financial administration of Lombardy, especially in provisioning, currency, weights and measures. Beccaria's lectures are models of precision and rigorous deduction, although he is of course not entirely free from mercantilistic misconceptions and concedes the value of protective tariffs.

In 1772 a chair of civil economics was founded at the University of Modena and the professorship was conferred upon Agostino Paradisi, distinguished both as poet and as prosodist. Although they lasted only eight years, Paradisi's

courses served to arouse thought and discussion in the field of financial and economic reform. He advocated the abolition of tax privileges, simplification of the tax system and more precise regulation of charitable institutions. When Paradisi retired, the chair was suppressed and was not reestablished until 1859 when Modena was politically reunited with Italy.

The following economists should also be mentioned in a review of the teaching of economics in Italy: Vincenzo Emanuele Sergio, professor of economics, agriculture and commerce (the chair was founded in 1779 in the R. *Accademia degli Studi* in Palermo and was retained until 1806), and Paolo Balsamo, who succeeded him in the academy, which had been transformed into a university some years earlier. By his effective teaching he spread Smith's doctrine in Sicily; he attacked barriers of all kinds, maximum prices, government contracts—in general all prohibitions which restricted agriculture and industry in Sicily—and even went so far as openly to declare himself in favor of international free trade.

As in the Universities of Pavia and Padua, the executive directorate of the Cisalpine Republic created a chair of political economy at the University of Bologna. It likewise founded chairs of public and international law, history of customs and laws, as integral parts of the faculties of jurisprudence. From 1801 to his death in 1828 Luigi Valeriani occupied the chair at Bologna. Although the chair of political economy had been suppressed in the reorganization of the University of Bologna undertaken by the papal government in 1824, by an exceptional ruling it was continued during the lifetime of Valeriani in consideration of his signal merit. Valeriani's teaching was indeed fruitful for the progress and the spread of the social sciences: his works are original, erudite and keen, especially in his treatment of the theory of value and of the relations between economic and juristic phenomena. Among his pupils was Pellegrino Rossi.

From this period of rather occasional teaching of social economics, we pass with the unification of Italy to a systematic period. In 1846 Piedmont effected the administrative reforms which cleared the way for the constitutional liberty and the purposive action of the political Risorgimento. In the faculty of jurisprudence a chair of political economy was instituted which was held by the young Neapolitan Antonio Scialoja. He had, a few years earlier, at the age of twenty-two (1840), published the

Principi della economia sociale which aroused the admiration of his colleagues because of its sound doctrine and its scholarly research. His lectures were attended not only by students but by such eminent Piedmontese as Camillo Cavour, Massimo d'Azeglio, Cesare Balbo—"by all that brilliant constellation of great minds and famous men that rose on the political horizon of Italy and anticipated the new era. And he conquered the souls of his hearers by his marvelous eloquence, and confounded them by the loftiness of his ideas" (Carlo de Cesare, *La vita, i tempi e le opere di Antonio Scialoja*, Rome 1879, p. 34). Scialoja continued to teach until the first months of 1848, when his desire to cooperate in the political regeneration of his native land caused him to return to Naples. There public opinion soon forced him into the councils of the king, who at that time seemed sincerely disposed to pursue the paths of liberty. After the reaction he was jailed with several other ministers. At Turin another *émigré*, the Sicilian, Francesco Ferrara, who had just emerged from that very Bourbon prison in which his predecessor was about to be shut up, succeeded to Scialoja's professorship. Ferrara taught at the University of Turin until 1859 and his courses were widely attended by very select audiences. According to Cavour, who speaks of them in various articles on the Risorgimento, they mark a "new era in the study of economic science in Piedmont." At that time he began the publication of the *Biblioteca degli economisti* and of those masterly prefaces in which he used the occasion afforded by these translated works not only to discuss their content but to proceed to his own analysis of scientific problems. He exercised great influence upon all Italian students by his profound wisdom, his spirited enthusiasm, his irresistible argument and his fascinating style; and it may be said that for several decades he occupied a prominent place in Italian economic literature.

After Italian unification, beginning especially with the third decade before the close of the nineteenth century, the study of the social sciences in Italy became completely, or almost completely, identified with the universities. This was in part due to the ordinances governing higher education. The original law of 1859 provided that all professorships were to be awarded competitively and that the competition was to be judged on the basis of scientific reputation. The contestants must prove

that they had mastered their subjects, and must give evidence of research ability. The functions of the *Privatdocent* were similar to those of the official professor. The position was and is conferred following tests of the candidate's ability to understand scientific truths and to disseminate the spirit of research. The greatest freedom of instruction is guaranteed; no programs are arranged other than those proposed by the professors themselves and approved by the faculty with a view to coordinating the various disciplines. These programs can be changed annually and there is no set mode for the presentation of a given subject.

Beginning with 1860 instruction was instituted in political economy, and in 1875 in statistics, in the faculty of jurisprudence, which comprised in addition the chairs of private law and of the philosophy of law and various chairs of public law. The ordinance of 1885 introduced into all Italian universities special chairs in the science of administration and finance, which had previously existed in only a few of the universities. Separate faculties of political and social science have been established only recently, in some universities only after the Gentile Law of 1923 gave them wider autonomy in determining their courses and in selecting their faculties. However, almost all the faculties of jurisprudence instituted schools and courses comprising subjects of a social and political nature which previously had not been specifically represented, such as economic history, history of economic doctrine, history of treaties, constitutional history, commercial policy, etc. They were empowered to confer the doctorate in social and political science, or in political and economic science, as well as in jurisprudence. These added courses, however, are almost always based upon various courses constituting the faculty of jurisprudence proper, which they complement. According to individual university regulations the doctor's degree in social science can generally be obtained by doctors of jurisprudence with two years or even a single year of attendance in special courses. Ever since the unification of Italy the institution of special faculties of political or of social and political science had been discussed, but the idea prevailed of maintaining the unity of the jurisprudence faculty, which was, indeed, becoming more and more a juristic-social rather than a purely juristic faculty. Professors of economics were able successfully to impart a scientific character to their courses, which were

widely attended, since students of jurisprudence considered courses in economics fundamental even for a strictly juristic training and the doctor's degree in jurisprudence was requisite for admission to many careers and public offices as well as to the practise of law.

In Florence the Istituto di Scienze Sociali, "Cesare Alfieri," founded in 1874, was more concerned with preparation for the diplomatic and the consular service than with purely scientific learning. The higher schools of commerce, with numerous professorships in economics, had a more or less professional cast, at least until recent years. The one at Venice, R. Istituto Superiore di Scienze Economiche e Commerciali, is an exception; since the beginning it has had a section for teachers and for the preparation of docents in economics in the secondary schools.

The revival of the study of the social sciences in Italy was, as we have said, promoted almost entirely by the universities. Luigi Cossa was a famous professor whose pupils either directly or indirectly included all the university professors of the last thirty years of the nineteenth century; among them should be mentioned Giuseppe Ricca-Salerno, Maffeo Pantaleoni and Achille Loria. Cossa had the spiritual and intellectual qualities that inspire scientific research, and he understood the aptitudes of his pupils, assigning to each the work to which he was most suited. Angelo Messedaglia, an eminent scholar who dealt with various economic, demographic and financial problems with gratifying results, was contemporary with Cossa. Scientific research, characterized by critical objectivity, advanced under these leaders and was extended to all fields of economics—doctrine, history and policy, demography, and methodology and application of statistics. It was a result of the impartiality which characterized these investigations that Italy never gave rise to any independent school of economics. Each investigator used the method most suited to the nature of his research and his inclinations. Chairs of sociology were established only in a few universities, relevant courses were given only occasionally, in certain years; but sociological research was pursued nevertheless by professors of philosophy, of demography and of political economy. Although political economists did not adhere to the materialistic interpretation of history, they constantly referred to the importance of the economic factor in the constitution of society and also devoted special

courses of lectures to the sociological doctrines.

The introduction of the study of political economy in the technical institutes likewise served not only to disseminate economic culture generally but especially to encourage scientific research, for several distinguished university professors began their academic careers in these institutes. In the universities there were institutes or seminars, with special libraries, attended by young men exceptionally qualified for scientific work. The first, which was called *Laboratorio di Economia Politica*, was instituted by Professor Cognetti de Martiis of the University of Turin in November 1893, and many of the pupils of that laboratory are today university professors with distinguished reputations in the fields of economics and social research. Since 1879 Siena has had a juristic institute with a special library and sections for economics and finance. Today all universities have these seminars for scientific training and advanced research. Many of them publish annals or reviews in which the memoranda and the papers of professors and students are collected. Moreover the reviews that are not the direct product of university faculties or schools publish papers that are influenced or inspired by the universities, the higher institutes or works of university professors. The academies encourage the publication of scientific studies by awarding prizes on topics that may or may not be specifically assigned. These writings in the social field, however, with occasional rare exceptions, are the work of university professors or their students.

AUGUSTO GRAZIANI

II. ITALY UNDER FASCISM. The two great figures which dominated the social sciences in Italy immediately before the advent of Fascism were Vilfredo Pareto and Benedetto Croce. Both of these scholars involuntarily contributed to the setting of the stage for Fascism. Pareto, the economist, led the attack on democratic institutions and conceptions of government and made a strong plea for genuinely scientific statecraft carried on by economic experts. Croce, the historian and philosopher, contributed largely to a self-conscious national tradition in thought and culture and erected a philosophic framework for the social sciences which was peculiarly a product of Italian experience. Although Pareto and Croce had little in common, the net outcome of their systems was to link politics and economics

closely together and to separate them from the moral ideas which the Catholic church on the one hand, and the French Revolution on the other, had associated with political life. Fascism continued to emphasize the economic factor in social science, but it refused to divorce morals, art and religion from politics. The Fascist doctrine that society is to be understood in terms of the clash of peoples or nations, and that each people must be a spiritual and economic unity which must be expressed by the sovereign and omniscient state, found its chief expression in three schools of thought: the idealistic school of Giovanni Gentile which glorified the state, at the expense of the church, as the embodiment of Italy's moral and spiritual life; the nationalist group of politicians, led by Enrico Corradini, who revived Italy's imperialistic ambitions and made a cult of Italian expansion; and Mussolini and his associates, who used their syndicalistic doctrines of violence and creative will first against the socialists and then against the democratic liberals. The implications of such doctrine for social science are that the various social disciplines must all be subordinated to politics; that politics itself is an art rather than a science; that it must be conducted by a small group of political experts or geniuses; and that these political experts must use and develop the social sciences as technical instruments for their art. In short, social science is conceived by the Fascists as primarily a technical discipline for statecraft, not a general subject matter for public education.

In practise this means that the elementary schools lay stress on patriotism, art and religion; that superior schools emphasize technical and vocational training in social science; and that universities are centers of research. All children are taught a practical familiarity with their national traditions and social institutions from the very start. They are taught a romantic kind of history and the conventional forms of religion, but the emphasis is always on the appreciative or practical aspect; they are taught to love their country, admire its heroes, sing its songs, practise its rites, etc. In the superior schools a restricted, selected fraction of the people is taught the technical detail of the operation of social institutions for professional use. History is treated more scientifically than in the elementary schools, and the teaching of philosophy and sociology is substituted for religious instruction. In the universities a still

smaller group is given freedom for research, for guiding the solution of social problems and in general for the development of a critical competence in social science. Of course much of this educational program is not characteristically Fascist. The chief innovations introduced by the Fascists were the teaching of religion in the elementary schools and the development of technical, vocational education in the social sciences in the superior schools. These are, however, merely applications of the fundamental principle that religion, morals, art and science are all but aspects of social organization, and as such they are to be subordinated to and supervised by the state, the organ and expression of the social unity of the nation.

The technical organization of social science teaching has undergone less change than the content of the instruction. The Fascist government was forced to proceed slowly in the reorganization of the universities, partly out of fear of arousing active opposition among intellectuals who were already cool toward Fascism, partly because of the pressure brought to bear by ambitious politicians who sought professorships as sinecures and as spoils of political victory. Nevertheless, immediately after the march on Rome, would-be professors began to expound various aspects of Fascist doctrine at the universities as *liberi docenti*. Courses were offered in the recent history of Italy (usually a camouflaged title for Fascist propaganda), in the principles of national syndicalism, in corporate law, in the theory of the state, etc. A second type of Fascist influence in the universities came from those regular professors who had joined the Fascist party and who naturally became Fascist leaders in university circles. Among these should be mentioned Alberto de Stefani, Giovanni Gentile, Alfredo Rocco, Sergio Panunzio, Gino Arias and Gioacchino Volpe. These scholars, and many others, have applied their knowledge of the social sciences to the cause of Fascism.

A special effort has been made to concentrate the teaching of the social sciences according to Fascist principles in a few universities. Most notable was the founding of the Fascist Faculty of Political Science at Perugia in 1928, where it is planned to train Fascist leaders intensively. Lesser centers of Fascist teaching have been established at Rome, Pavia, Padua, Florence and Bologna. At Bologna there is a "Fascist University" which is really little more than a group of courses organized by Fascist students

and teachers for the spread of Fascist propaganda. The Istituto Nazionale Fascista di Cultura, which is more serious in nature, was established by Gentile at Rome. Its official organ is *Educazione fascista*, and it enjoys the cooperation of a number of reputable scholars.

At every university there is a Fascist student organization which serves as a social club, as a center of propaganda and political activity and also as a means of encouraging serious political studies. Edmondo Rossoni, the Fascist labor leader, has recently established a Labor University, but little can be said as yet of its activities or probable success.

Far more typical of Fascism, however, than these academic agencies of social science, are the research bureaus which are directly attached to the government. Most significant of these are the various federations of syndicates and the ministry of corporations, which is really a bureau for the cooperative solution of the nation's economic problems. Here the secretaries of the federations of syndicates and other experts are summoned, as need may arise, to investigate sources of conflict, waste or disorder among the various economic groups or interests of the nation. Closely allied to the ministry of corporations are the compulsory labor tribunals. These courts, in cooperation with the ministry of corporations (under the leadership of G. Bottai) and the ministry of justice (headed by Alfredo Rocco), are constructing a new body of law, dealing in a new way not only with labor problems but with almost every imaginable phase of economic activity. The codification and reconstruction of Italian law is in itself an enormous task assumed by Rocco and already well under way.

Several agencies dealing with specific problems have been created by the Fascist government, e.g. the Institute for Exportation, the Institute for Emigration and the Central Bureau of Statistics. No doubt the most vital and effective research now being done in Italy is being carried on by these non-academic agencies.

The Fascist theory is that social science is, or ought to be, in the service of the state. Hence the demand is constantly made by Fascist politicians that the universities be "purified" of all anti-Fascist elements and teaching. In a famous speech in the Chamber of Deputies on the Law of April 3, 1926, Mussolini said: "The professor fulfils a function in national life much more delicate than that performed by the official of a public service or by the

magistrate. The professor, who molds minds and consciences and can make of men either heroes or cowards, has an extremely important function in the life of the nation. Hence he must be an atom, not a group or association, in the state." In other words, associations of professors, like associations of public employees, have no legal status in the Fascist syndical law, and the principle enunciated is that the more vital a person is to the life of the nation the less liberty he has. At least one economist has been forced to resign and a number of others have been intimidated by violence or threats of violence; and in general no pretense is made of respecting academic freedom. In spite of this theory many social scientists who are not Fascists are still tolerated in the universities.

The press has been more quickly and thoroughly "Fascisticized." Editors are expected to avoid publishing political debates, discussions, council proceedings and in general anything reflecting the presence of various points of view, and to publish only the results of the deliberations, thus giving the appearance of unanimity, "discipline," and successful cooperation within the Fascist ranks. The public is supposed to know outcomes of issues, not to participate in their discussion or solution. But here again the theory is more stringent than the practise, and anyone who knows how to

read between the lines can get a fair amount of political discussion from Italian newspapers.

It goes without saying that all the agencies of political science which we have mentioned receive their financial support either through local governments or *fasci* or through the central government. In addition the government has lent its support increasingly to various agencies of social welfare which have no immediate political functions. The compulsory syndicate tax serves to support most of such institutions. Among them should be mentioned the *Dopo Lavoro* (a national agency for the education and recreation of laborers), the Association of War Cripples and Invalids, the Institute of Insurance, the Institute for the Protection of Maternity and the Institute against Tuberculosis. A special effort is being made to increase the production of grain by means of prizes, exhibits, lectures, etc. In general the government is most active in fostering agricultural science, drainage, irrigation, hydroelectric engineering, etc.

In short, practically all organizations of public import are being "protected and disciplined" by the Fascist government. Only the church has retained its independence, and even it has sacrificed some of its social organizations to the secular government and has stopped the political activities of others.

HERBERT W. SCHNEIDER

VI

Russia

I. IMPERIAL RUSSIA. The history of Russian universities begins with the foundation of the Imperial Academy of Sciences, established in 1724 partly according to the conception and plan of Leibnitz. This institution, located in St. Petersburg, was throughout the greater part of the eighteenth century something more than an ordinary academy; it was also the first Russian university. Like all the universities of that time it was a combination of secondary school and higher school of the university type. Until 1733 there was not a single Russian among the members of the academy, there were more teachers than students in its university classes, and it had to depend not only on foreign professors but also on foreign students. It was, moreover, very difficult to maintain regular and uninterrupted teaching. Nevertheless there were courses in the social sciences; among them were law (including Russian law), moral philosophy, history (including Russian history), and Roman and Greek antiquities, although as a rule they did not occupy the foremost place in the academy. In these fields the works and teaching of S. Th. Bayer (who entered the academy in 1725), G. Fr. Müller (1731), J. E. Fischer (1732), Strube de Pyrmont (1738), A. L. Schlözer (1765) and J. G. Stritter (1779) laid the foundation for the scientific study of Russian history, law and institutions. Even the work in natural sciences, the primary interest of the academy, was, in both research and teaching, of some importance in the development of the social sciences. The naturalists of the St. Petersburg academy were perhaps the first learned statisticians in Russia and the first to expound there the conception and practise of statistics.

Although university teaching in general and that of the social sciences in particular had its inception in St. Petersburg, the real development of the social sciences began in the University of Moscow. The first professors of that university, which had been from the outset divided into three faculties (law, medicine and philosophy), were drawn partly from the Russian graduates of the St. Petersburg academy

and partly from abroad. In the faculty of philosophy, general and Russian history were taught in addition to philosophic subjects. Among the purely social sciences in the faculty of law in its initial period, we find natural law, international law, Roman law, public law of the Holy Roman Empire, general and Russian jurisprudence, and politics. All of these subjects were taught by Philip Heinrich Dilthey, who had been specially invited from Vienna and who for a while embodied in his own person the entire faculty of law. Although at first he lectured apparently only in Latin and French, Dilthey soon learned Russian, familiarized himself with Russian law and became the founder of academic jurisprudence in Russia. Two future professors of law and several statesmen were graduated from the University of Moscow during its first eight years. The two professors, Desnitsky and Tretiakov, studied later at the St. Petersburg Academy of Sciences, and were then sent as university stipendiaries to Scotland, to the University of Glasgow. There they became the pupils of Adam Smith and the followers of David Hume. Tretiakov died early (in 1776), leaving only a small historico-economic treatise, in which he had expounded some of Adam Smith's ideas four years before the publication of the *Wealth of Nations*. Desnitsky was active for twenty years as teacher and scholar, succeeding Dilthey at Moscow University. He enriched Russian legal literature with a translation of Blackstone's *Commentaries*, excellent for its time but unfortunately incomplete, published in Moscow in 1780-82 by special command of Catherine II. Foreigners continued to appear in the law faculty of Moscow University, although in 1768 the Empress Catherine, at the very height of the nationalist and liberal period of her reign, proposed that lectures in the university, and especially those in connection with the faculty of law, should henceforth be delivered in Russian. From that year on, Russian became the principal language of instruction.

At that time university teaching was practically confined to general courses, based on

printed textbooks which had to be approved by the university authorities. Among the approved authors in the social sciences were Pufendorf, Nettelbladt, Heineccius, Vattel, Bielfeldt, Achenwall, Pütter, Montesquieu. A course of lectures by Professor Schneider, giving an exposition and interpretation of Montesquieu's *De l'esprit des lois*, was published in Moscow in 1782 in Russian and French. Toward the end of the eighteenth century Kant's influence left its mark on the philosopher Schaden, who lectured after 1776 on natural law and politics and was the teacher of the great Russian historian Karamzin. Apparently no instruction in political economy was given at the time at Moscow University, but economic policy was taught as a part of political science. Once during this period a course on private economics was announced. Statistics, as understood by Achenwall, was taught in connection with history almost from the founding of the university. In 1773 Professor Reichel published in Russian a short textbook on the statistics of the principal European countries. In jurisprudence the practical as well as the theoretical aspects were continuously stressed. The successor of Dilthey and Desnitsky was Goriushkin, a practical jurist, himself a judge and a high official, a specialist in positive law and the author of practical textbooks on Russian law and procedure.

Closely allied to the scientific and academic life of Russia, especially of Moscow, was the publishing activity carried on in connection with the university by the famous educator, the freemason N. I. Novikov. His friend and associate in editorial work was Johann Georg Schwartz, professor of philosophy and of the German language. Novikov's activities were at first limited and then suppressed during the reactionary period of Catherine's reign, but in spite of that a considerable cultural impetus was given to Russian public life, and a great bulk of educational matter, such as historical sources of great value, became accessible to the public, thanks to him and his associates.

With the beginning of the nineteenth century a revival of Russian academic life became apparent. New elements, both Russian and foreign, were injected into the University of Moscow. The Göttingen professor, Meiners, author of many books on the history of civilization, including a standard work on the universities of Germany, was the principal counsellor of M. N. Muraviev, who was then curator

of Moscow University and active in efforts to reform it. During this liberal epoch political economy was becoming especially popular in Russia. The works of Adam Smith, Herrenschwand, Verri, Alexander Hamilton and many other writers were translated into Russian. The influence of Jeremy Bentham was also felt at this time. Chairs of political economy were established in the Academy of Sciences, in the University of Moscow and in such other newly founded universities as those at Dorpat (1802), St. Petersburg (1803), Vilna (1803), Kazan (1804) and Kharkov (1804); the subject was taught in the faculty of moral and political sciences. Among its teachers were such distinguished men as Heinrich Storch, at the academy, Christian Schlözer, who lectured at Moscow University in German and French, and the Kantian, Jakob, at Kharkov. During the academic year 1806-07 the first course on finance was given in the University of Moscow. About the same time statistics, taught as a part of history in the faculty of letters at Moscow, was intrusted to a special professor of statistics, Grellmann. After him it was for a long time taught by Heym, originally a philologist, who later specialized in statistics and geography and also lectured, sometimes publicly, on the theory and practise of commerce. In 1821 Stepan Maslov, in standing for the degree of doctor of moral and political sciences, defended in the University of Moscow a printed Latin thesis on the scope and history of political economy.

The same period witnessed the definite establishment of the practise of sending young Russian scholars abroad for study, and henceforth they were dispatched in large groups. As early as the eighteenth century the Academy of Sciences and Moscow University were sending young Russian scholars to complete their studies in foreign universities. The University of Göttingen and, to a lesser degree, the universities of Leipzig and Strasbourg acquired in this way a special importance in Russian academic culture. In 1808 twelve scholars, provided with special instructions, were sent from the University (Pedagogical Institute) of St. Petersburg, some of them students of economics and law. Likewise in 1828 and 1834 the universities had to nominate candidates to be sent abroad to study, with the understanding that they were to be chosen on the basis of an examination in the Academy of Sciences. Upon their return to Russia the young law scholars were examined by a commission con-

sisting of professors and practical legal experts, according to a program drawn up by the great Russian statesman and jurist, Speransky. In this manner the future distinguished professors of public and administrative law (Redkin and Leshkov), of Roman law (Krylov), of criminal law (Barshev) and of political economy (Chivilev) were selected for the University of Moscow.

In 1835, by a new general statute concerning the universities, the separate faculty of law which had originally existed in the University of Moscow was restored. In it the following subjects were to be taught: philosophy and methodology of law, public law of Russia, Roman law and its history, history of Russian law, civil law, criminal law together with security police, welfare police (administrative law), financial law (finance), diplomacy and international law, and ecclesiastical law. After the closing of the universities of Vilna and Warsaw, courses on the system of law which was still in force in Poland were given in the University of Moscow, partly by former professors of the two universities named. Political economy and statistics, which was still understood in Achenwall's sense as a descriptive part of political science, were by this statute transferred to the faculty of history and philology. However, by the more liberal statute of 1863 they were restored to the faculty of law. With unimportant changes the subjects here enumerated cover all the disciplines taught in the faculties of law until the time of their suppression by the Soviet government. Under the statute of 1835 the teaching of the social sciences finally assumed its real university character, preserving at the same time a close contact with the needs of the outside world. Practical teaching of jurisprudence attained at that time a very high degree of perfection, since the number of students was small and the character of the teaching staff was showing constant improvement.

Although the fluctuations of government policy affected the character of university teaching, this influence must not be exaggerated. The excitement during the reactionary period of the reign of Alexander I, caused by the reprisals against the liberal professors of the universities of St. Petersburg and Kazan, lost its force in the following reign, when the whole matter was formally dropped. Of particularly great moment for the freedom of university life was the fact that under the auto-

cratic regime of the nineteenth century the Academy of Sciences, being exempt from outside censorship, preserved an absolute independence in matters of learning. The statute of 1804 directed that "every professor shall choose for his lectures one of his own works or that of another well known man of learning; in both cases the work so chosen shall be submitted for consideration to the University Council and if the Council thinks fit to introduce any changes into it, the professor, after having made same, shall submit them to the Council for approval." The statute of 1835, however, no longer contained this provision. Professors therefore achieved a greater independence, and the principle of freedom in teaching became so well established that it persisted as the leading principle of Russian university life. Whenever deviations from it took place they were due to political pressure, directed to the selection of professors (discriminating against those regarded by the government as politically undesirable) or to the selection of courses to be included in the curricula. Examples of the latter are the suppression, in the reign of Nicholas I, of the teaching of *jus naturae* and later of secular philosophy, and also the reactionary university reform of 1884.

Of the various social sciences, the greatest success, both in teaching and in training for research work, was achieved at this time in connection with Russian history, including legal history in the widest sense of the term, and also economic history. The founding of Russian history as a discipline may be ascribed to Gerhard Friedrich Müller and the Göttingen professor August Ludwig Schlözer, both of the St. Petersburg Academy. Considerable influence was also exercised by Johann Philipp Gustav Ewers of Dorpat University. Since the beginning of the nineteenth century this university, through its special institute for the training of Russian professors, had played a very important part in university education. Beginning with the thirties and forties Moscow University became the center of the systematic cultivation of Russian history, especially through the work of Mikhail Pogodin, a pupil of Heeren, and Sergei Soloviov, a disciple of Guizot, Ranke and Ritter. At the same time in St. Petersburg some particularly fruitful work in legal history was being done by Nevolin, author of the classical *History of Russian Civil Law* (in Russian, St. Petersburg 1851) and of a remarkable introductory textbook on law, translated at the

time into German. Russian history was at that time turning to a systematic study of historical sources, a great number of which were then being discovered and published. Legal and political history were greatly in advance of economic history. Church history, with its important social aspects, was intensively studied in the ecclesiastical academies, especially in Moscow, Kazan and Kiev.

The fundamental institutional changes of the sixties could not but affect the social sciences. The number of universities did not appreciably increase, but the number of students grew exceedingly and teaching became specialized. The dual role played by the universities became more conspicuous: they served as training grounds both for the professions, especially public service, and for scientific research work. Their standards of vocational instruction showed a decline. Thus the study of jurisprudence was, for the average student, practically reduced to a series of examinations whose nature depended almost entirely on the personality of the examiner. There were several reasons for this: the unsatisfactory character of the teaching in the schools preparing for the university; the overcrowding of universities; the absence of a clear conception of the fundamental difference between elementary university education and training for research work. At the same time universities were rapidly improving as training schools for future scholars. In spite of its general reactionary nature the university statute of 1884 proved helpful by introducing the German institution of *Privatdocent*, and the principles of free teaching and free choice of courses by the students. The scholastic work of each individual student was also intensified by the development, especially in the nineties, of the system of seminars and pro-seminars.

The greatest progress in training future scholars was made in the field of history, partly because of the large number of gifted teachers in the field. In the University of Moscow Vladimir Guerrier was the founder of seminar training for students of history in its broad sense. His work was continued and expanded by Paul Vinogradoff. Somewhat later Kliuchevsky and his pupils (among whom Miliukov, Liubavsky, Kiesewetter and Bogoslovsky occupied the first rank) exercised great influence. In Kiev historical schools were founded by I. V. Luchitsky, known by his investigations into the social history of France before and

during the revolution, and V. B. Antonovich who contributed to the study of the social history of southwestern Russia. In the University of St. Petersburg a school of Byzantology was founded by V. G. Vassilievsky who was chiefly interested in the social history of Byzantium. Another eminent Byzantinist was Fedor Uspenski of Odessa. Some fruitful work in general history, especially that of France and Poland, was done by N. I. Kareyev. A. S. Lappo-Danilevsky (of the Academy of Sciences) and S. F. Platonov, both lecturers in the University of St. Petersburg, did important work in Russian economic and social history. In the last decade before the 1917 revolution the activity of Rostovtzeff in the same university was of considerable importance for the study of the economic and social history of the ancient world.

In the general theory of law and public law a great influence was exercised in St. Petersburg by A. D. Gradovsky, N. M. Korkunov and L. I. Petrazycki; in Moscow at first by B. N. Chicherin, then by M. M. Kovalevsky (who, however, had to leave the university for political reasons), A. S. Alekseyev and P. I. Novgorodtsev. In the history of Russian law a great number of students were trained by M. F. Vladimirsky-Budanov in Kiev, and F. I. Leontovich in Odessa and Warsaw; at St. Petersburg Professor V. I. Sergueyevich, although an excellent lecturer and a great scholar, had no gift for training individual students. In Roman law the outstanding names were S. A. Muromtsev in Moscow, later speaker of the first Duma, Joseph A. Pokrovsky in Kiev, and David Grimm in Dorpat and St. Petersburg. Least successful was the training of research workers in such practical disciplines as civil and criminal law; in this direction legal practise in the reformed courts was of a much greater significance than university teaching.

The destinies of political economy and statistics took a peculiar course. Until recently progress in economics was not fostered primarily by the universities, but rather by the political and economic sections of the so-called "thick" reviews, which were not subjected to preliminary censorship. This situation was similar to that which existed in England in the early nineteenth century when the principal instrumentalities for the dissemination of economic knowledge were books, pamphlets and magazines rather than university teaching. Statistics being treated primarily as a special adjunct to

public administration, the best publications in the field, even when not strictly official, were not by university scholars but by persons in the government service, where the most adequate statistical training was to be found. Interest in statistical and descriptive economic studies was also stimulated by two learned societies which enjoyed the protection of the government: the Free Economic Society, founded as early as 1766; and the Geographical Society, founded in 1845. In the last quarter of the nineteenth century the statistical departments of the units of local self-government (*zemstvo*) had come to occupy a preeminent place as schools for Russian statisticians. *Zemstvo* statistics, though influenced by A. I. Chuprov, professor of political economy and statistics at the University of Moscow, and by A. F. Fortunatov, professor of agricultural economics in the Higher School for Agriculture in Moscow, can by no means be said to owe its existence to the lectures and studies of academic scholars. In the beginning of the twentieth century, however, a leading role in statistics was assumed by two university professors: A. A. Chuprov, master of mathematical statistics, and A. A. Kaufman, who became professor only after a long practise as administrative statistician.

One of the peculiar features of Russian economic teaching was the independent place allotted, after 1835, to public finance or, as it was officially called, "financial law." It was formally elevated to the rank of an independent discipline, and a special chair was created for it, as well as special degrees of master and doctor of financial law. Usually, however, at least until the twentieth century, it was taught by ordinary economists. Among the particularly prominent teachers of finance were: in Moscow, Yanzhul, Ozerov and Haensel; in St. Petersburg, Lebedev at the university, and Friedmann and Tverdokhlebov at the Polytechnic Institute; in Kiev, the Yasnopolskys, father and son, and Silin; in Kharkov, Migulin and Alekseyenko, who afterwards became a competent chairman of the budget committee in the Third and Fourth Dumas of the empire. However, few persons studied for a degree in financial law, and this separation of finance from economics, unknown either in Germany or in England, was scarcely a judicious measure.

Economic history was cultivated in the Russian higher schools both by historians and by economists. The most important contribu-

tion to the teaching of that subject was made by two historians, the mediaevalist Vinogradoff and the Russian historian Kliuchevsky. In the department of economics of the St. Petersburg Polytechnic Institute, economic history was a compulsory subject, its teaching being entrusted to one of the professors of political economy. The chair was occupied first by Ivaniukov and then by Struve. The courses given by the latter contained an exposition of historical sociology of economic life, industrial economics and commercial policy. In the law faculties of the universities economic history was an elective subject. In St. Petersburg it was for a long time taught by I. M. Kulisher, author of the most popular textbook of European economic history. Instruction in economic history was often combined with the history of economic theories. Such combined courses were delivered by A. I. Chuprov in Moscow, V. Levitsky in Kharkov, and S. Bulgakov in the Moscow Institute of Commerce.

Sociology was not taught until very recently in Russian universities or similar schools, but the sociological method, older and more influential than the formal science of sociology, was for a long time applied to the study of law, history and economics. In academic circles the outstanding sociologist was Nikolay Kareyev, a professor of history and author of numerous historico-philosophical and sociological works. He was closely connected with the Russian sociological school of Lavrov and Mikhailovsky. This group, although scantily represented in the halls of official learning, has made probably the most important Russian contributions to sociology in the nineteenth century. The researches of M. M. Kovalevsky, historian of legal and economic institutions, gave a considerable stimulus to the development of genetic sociology. With his assistance the well known Russian neurologist, Bekhterev, founded in St. Petersburg the Psycho-Neurological Institute, the first higher school in Russia where sociology was taught under its proper name.

A great improvement on the old university teaching, which provided no adequate vocational instruction in social science, was furnished by the department of economics of the St. Petersburg Polytechnic Institute, a new type of school established in 1903 on the initiative of the minister of finance, S. J. Witte, and of the famous chemist, Mendeleyev. Political economy and statistics, taught in the faculties of history and philology or, after 1863, in the faculties of

law, were naturally subordinated to the major disciplines professed in these departments. In this new school and in the institutes of commerce modeled after it, instruction in all the economic sciences, including finance, was given on a very large scale, and the law disciplines were represented in proportion to their relevance to the study of economic institutions. Thus a prominent place was given to constitutional and international law and to civil and commercial law; some criminal law was taught, but no courses were given in Roman (*sensu stricto*) and canon law.

In this new school at St. Petersburg, elementary instruction in statistics and economic geography, which practically amounted to descriptive economics operating chiefly with statistical data, was given by two, and later three, special tutors who were themselves practical statisticians. Working under the general guidance of V. E. Dehn and A. A. Chuprov they coached individual students by offering them a series of concrete problems whose solution required familiarity with statistical sources and technique and the specific application of economic reasoning. This organization of practical exercises, unusual in Russia, determined the success of this school in the training both of practical statisticians and economists and of research men in these fields. For the latter valuable lessons were to be learned in the statistical seminar of A. A. Chuprov, which produced a series of valuable monographs; in the economic seminar of V. E. Dehn and P. B. Struve, which was engaged in a number of research projects in all branches of theoretical, historical and applied economics; and in the seminar on finance of M. I. Friedmann, later carried on with the participation of V. N. Tverdokhlebov. In the Moscow Institute of Commerce similar work was conducted by the late A. A. Manuilov and I. M. Goldstein. Numerous researches in descriptive economics, chiefly of Russia, originated in their seminar.

From the preceding description it is clear that the social sciences in Russia were considerably influenced both as systems of ideas and as teaching disciplines by borrowings and adaptations from abroad. As early as the eighteenth century the practise was inaugurated of sending young scholars to foreign countries. It continued in force until Russia was isolated by the World War and the revolution. After graduation the ablest of the students became stipendiaries either of the universities, which always disposed of

relatively large funds for this purpose, or of the corresponding government departments. The purpose of such traveling scholarships, however, changed substantially in the course of time. Originally young men were sent abroad to study in the literal sense of the term. Thus in the eighteenth century Lomonossov was studying with Christian Wolff in Marburg, and many other Russians with Achenwall in Göttingen. Later on the chief object of traveling scholarships was to enable young Russian scholars to study foreign sources and literature and to familiarize themselves with the conditions of scientific work prevailing in other more advanced countries. Fellows sent abroad were expected to render reports on their studies and observations, which were sometimes published. Such reports, published in the sixties in the *Zhurnal* (Journal) of the Ministry of Education and in many cases written by persons who afterwards distinguished themselves as scholars and teachers, form an extremely interesting source for the study of scientific life in Europe from the Russian point of view.

Familiarity with European culture led to an understanding of foreign systems of thought and made possible their adaptation to the peculiar problems with which Russian social sciences were confronted. Since the beginning of the nineteenth century Russian thought had been swayed by the same intellectual currents which dominated the rest of Europe. In the first half of the century the idealistic philosophy of Schelling and Hegel exercised a strong influence. Of the Russian Hegelians the best known was the Moscow professor of public law, B. N. Chicherin, a legal historian and philosopher of great penetration. In the fifties, sixties and seventies of the nineteenth century the influence of Comte, Spencer and J. S. Mill was dominant, and the latter's *System of Logic* was studied intensively in the law faculties. The influence of Buckle in the sixties and seventies of the last century is obvious even in the works of Soloviev and still more in the works of Shchapov and Nikitsky. Robert von Mohl and Lorenz von Stein were the standard authors in the field of political science. With A. L. Block, of the University of Warsaw, Stein's ideas were blended with a peculiar sociological nationalism of Slavophil coloring. The influence of Marx, in many points akin to that of Stein, was of course very great. Later the doctrines of Simmel, first introduced into Russia by the writings of Struve and the

university lectures of Kossinsky in Odessa and Kiev, acquired a considerable following.

As early as the forties of the nineteenth century the university teaching of statistics in Russia fell under the influence of Quetelet. It appears that his first Russian followers were Roslavsky-Petrovsky in Kharkov and J. Vernadsky, then of Moscow University. Economic thought was dominated in the seventies, eighties and nineties by German "socialism-of-the-chair," often mingled with the doctrines of Rodbertus and of Marx. The most influential teachers of political economy in Russia at that time—Chuprov, Ivaniukov, Issaev, Kablukov—were representative of that trend of thought. While their theoretical views were akin to Ricardo and still more to Marx, in the field of agrarian policy they rather sympathized with the Russian variety of socialism, the so-called populism (*narodnichestvo*) with its idealization of the village community. The main bulwark of economic liberalism, mixed with moderate "historism," was in this period to be found in the University of Kiev where the teaching of political economy and economic policy had been put on a firm footing by N. Ch. Bunge, founder of a real school of his own; his work was taken up by his pupil D. I. Pikhno and in the twentieth century continued by Pikhno's pupil A. D. Bilimovich. The influence of Jevons, Walras, Menger (as theoretical thinker, not as methodologist), Böhm-Bawerk and Wieser was not felt until very late; it blended in a peculiar way with the enormous influence of Marx and Marxism. It is curious to note that at the department of economics of the Polytechnic Institute in the period 1912-17 the populists Ivaniukov and Posnikov were succeeded by two former Marxists, Tugan-Baranovsky and Struve.

The development of scientific studies is vitally affected by the system of selection of the teaching personnel for schools of the university type. The Russian system, although orderly and well conceived, was characterized until the revolution by undue and harmful formalism. Any university graduate was entitled to be admitted to the so-called "magisterial" examination on a group of subjects pertaining to the faculty in question. As it developed towards the end of the nineteenth century this examination was essentially calculated for persons intending to devote themselves to scientific or professorial work. Those who passed it were entitled after two trial lectures to become

Privatdocenten in the appropriate discipline. The faculties, however, were allowed to admit as lecturer any person who had gained a reputation as a scholar, even though he had not passed the examination.

For the degree of master of a particular science (the first scientific degree) it was necessary also to defend a special thesis (dissertation); this, after 1863, had to be submitted in printed form. The examining board of the respective faculty was entitled either to admit that thesis for defense or to reject it, and it could pronounce the defense itself to be satisfactory or not (although in actual practice it was seldom refused). At first the thesis was not required to be scientifically independent and original, but from the seventies of the last century the *usus* of all the universities required that it be a piece of original research. Under the university statute of 1884, and up to the revolution, the defense of a thesis did not *ipso facto* confer any special rights upon the person who had defended it; he remained *Privatdocent*. However, by virtue of a special act which had to be ratified by the emperor, masters were often admitted to fill the functions of extraordinary and even of ordinary professors. Shortly before the revolution, when the office of regular docent which existed under the statute of 1863 was reinstated, the granting of a master's degree conferred a formal right upon its recipient to fill that office. The second and the highest degree, that of doctor, was granted when a second printed thesis was defended. It conferred upon its recipient a formal right to professorship.

This system, which in its main features originated in the first half of the nineteenth century and which was incorporated in the statute of 1863, encouraged the development of Russian learning in its crucial early stages. In the course of time, however, the shortcomings of the system became increasingly evident. Anyone who had passed the magisterial examination could obtain the right to teach in the higher schools, even though he had not published a single scholarly work. On the other hand a person who had scientific works to his credit but who for some reason had not passed the magisterial examination could become a *Privatdocent* with the permission of the university authorities, but had no chance of getting a professorship unless it occurred to some university to grant to him a doctor's degree *honoris causa*. In other words, a man's ability

to fill a professorial office was determined by a purely external test and not by any appreciation of his intrinsic qualities as scholar. As a result there could often be found among the professors persons who had completely fulfilled the formalities required of them, but whose qualities as scholars were almost negligible. Just before the revolution it became clear that some kind of reform was urgently needed in the organization of university promotions and admissions to professorships.

PETER STRUVE

II. SOVIET RUSSIA. In pre-revolutionary Russia the social sciences were taught in the eleven universities in the faculty of law and the faculty of history and philology. In the former were trained the lawyers and officials of bourgeois Russia; in the latter the instructors of secondary schools. With the collapse of the capitalist order the need for lawyers declined very considerably, and professional officialdom was dispensed with in the Soviet administrative machinery, which is run in large part by elective officials and for the rest by amateurs among the more intelligent workmen and peasants. The superfluity of law faculties was so patent, and they were so obviously breeding nests of reactionary ideologies and counter-revolutionary opinions, that at first they were suppressed altogether. Later, when a sufficient number of jurists with a thorough Marxist background were trained, several law faculties were reopened under the name of faculties of Soviet law. Their purpose is primarily to prepare court and prison personnel—judges, prosecutors, criminal investigators, members of commissions on child delinquency, juriconsults, notaries—and officials for the diplomatic and commercial representations of the Soviet Union abroad. Soviet law faculties exist now in five out of thirteen universities of Russia proper (Russian Socialist Federation of Soviet Republics): Moscow, Leningrad, Saratov, Kazan and Irkutsk.

The transformation of the faculty of history and philology was somewhat similar to that of the faculty of law. After the revolution these faculties were no longer needed, because the training of teachers for secondary schools was taken over by pedagogical faculties and institutes organized especially for that purpose. They were used therefore as the basis for the faculties of social science, established soon after the Soviets came into their own. Some

of their departments served as a foundation for the faculties of anthropology. At present there are faculties of anthropology in Moscow, and of linguistics and history of material culture in Leningrad. These are engaged principally in the training of ethnographers for work among the numerous nationalities of the Soviet Union and also of staff members for the many museums; to some extent they also prepare students for future scholarship in the field of ethnography, linguistics, history and archaeology.

Having thus reduced by more than half the number of old faculties in which the social sciences were taught, the Soviet government has developed extensively the system of higher schools of economics. Their pre-revolutionary prototype was the institute of commerce, founded and supported largely by individuals and private organizations. After the revolution these served as nuclei for institutes of national economy with a considerably extended teaching program. The largest of them, the institute named after Plekhanov in Moscow, may be taken as typical. It consists of three faculties, electrical-industrial, technical and economic, and is thus a combination of a technical and an economic school. Although the faculties are quite independent and have different programs, nevertheless the bringing together under one roof of technology and economics makes it possible to train the type of graduate wanted—a practical economist well oriented in technical disciplines and having a broad economic outlook. The social sciences taught in the first year in the economic faculty are economics and economic geography, European, American and Russian economic history, and statistics; additional courses are given in higher mathematics, physics and chemistry. In the second year, besides a continuation of general economics, there are special courses in the economics of industry, public finance and business law, and courses in technology and the qualities of merchandise. In the third year the students are divided among the commercial, industrial and statistical sections; all of the students, however, take courses in international economics, Soviet economic policy, history of economic doctrines, agricultural economics and business law, as well as the third year of general economics. In the sections there are certain compulsory subjects; in the industrial section, for example, the requirements include the economics of Russian industry, business cycles, industrial statistics,

industrial accounting, labor law, and special elective sequences for separate branches of industry (metals, textiles, petroleum, coal mining and leather). The Industrial-Economic Institute named after Rykov in Moscow, the Institute of National Economy named after Engels in Leningrad, the economic faculties of polytechnic schools and of the Timiryazev Agricultural Academy, are similar to the Plekhanov Institute.

In addition to the organizations named, in which the social sciences constitute the chief subject of study, there are a number of special schools in which these sciences are taught. To this group belong in the first place pedagogical faculties and institutes, of which there are eighteen in Russia proper. They have special social-economic departments comprising two sections, that of the science of society and that of economic geography. The first offers training to teachers of social science in the secondary schools, the second prepares for the same schools teachers of economics, economic geography and statistics. The teaching program of these sections includes economics, statistics, European and Russian history, elements of constitutional and economic law of Soviet Russia—in short, the same subjects that are taught in the institutes of national economy and in the faculties of Soviet law and of anthropology, but in a less specialized form. For instance, general economics is given in these departments only for seven hours a week in the first and second years (two hours of lectures, two hours of elementary seminar and three hours of advanced seminar work), while in the Plekhanov Institute the same subject is allotted ten hours for three years (four hours of lectures and six of seminars).

The teaching of the social sciences in the universities and institutes of Soviet Russia is not limited to the comparatively special courses described above. There is no faculty—not even the medical—in which some phase of social science is not taught as a subject of general educational value, for the government believes that no expert, however technical the character of his work, can be really useful in the Soviet state unless he is socially minded. Thus in the medical faculties are found provisions for seven hours a week of social science in the first two years of study. In the schools of geodesy twenty-two hours a semester are given to social sciences, or 6 percent of the entire number of hours; in the schools of agriculture these sci-

ences account for 6.5 percent of the total study program; in the department of metallurgy of the Moscow Mining Academy (just as in other faculties of the same type) they amount to 5.5 percent of the program. A considerable part of these courses is of a practical nature and is intended to convey to the students concrete information on Soviet constitutional law and economic policy, on trade unionism, etc. The latter is of direct interest to the students, all of whom are members of trade unions. However, courses of a theoretical character are also given. Of this nature are the courses on historic materialism and on general economics. In their practical aspects these courses are adapted to the interests of the particular vocation for which the school trains its student body. Thus in the industrial faculties more time is devoted to the industrial policy of the Soviet state and to labor law. In departments of agriculture emphasis is laid on the agrarian policy of the Soviets, rural social relations, etc.

A sequence of courses in social science forms a compulsory part not only of higher education but also of general primary and secondary education. The elements of social science are included in the programs of all schools, beginning with the fifth year. In this year a separate single course is given, combining the elements of economics, political science and history. It starts with a general characterization of industry; by using concrete examples some notion is given of the superiority of large scale machine production over small. Then follow data on the position of the working class prior to the revolution and at present, on the conditions in the village before and under the Soviet government, and on the economic and cultural ties between the city and the country. In the sixth year the pupils learn of the important developments in the economic life and social history of foreign countries (the industrial revolution, the French Revolution, the international labor movement, etc.). The seventh year is devoted to the modern period. The course begins with a description of the system of imperialism, which is followed by a detailed account of the history of this period (especially in Russia) and a comparison of the constitutions of the members of the Soviet Union with those of other states. In the eighth and ninth years more specialized courses are given in the same subjects, approaching in their scope those offered in the universities. Before the eighth year the teaching of history does not go farther back than the

eighteenth century, but in the last two years feudalism, the age of discoveries and the sixteenth and seventeenth centuries are covered.

The social sciences are also taught in a number of schools for adults, such as workmen's faculties (special schools preparing workmen for the universities) and Sunday universities. In content the courses given there do not differ from those just described, although in matters of exposition they are adapted to the age and background of the student body.

The fact that the social sciences in one form or another are now taught in all schools of the university type is responsible for a large demand for social scientists with professorial qualifications. At the very start the problem of training a considerable number of such persons was the most urgent that confronted the Soviet government in the field of higher education. The government made a brave beginning by establishing in 1921 the Institute of Red Professors, at that time a series of seminars for young Marxists. Since then the training of a university teaching personnel has been systematized and organized on a much larger scale.

At present the abler graduates of universities who choose a professorial career become "aspirants" and are granted scholarships by various institutions. The scholarship covers a term of three years, and at the end of that time the aspirant is supposed to present and defend at a public debate the results of his independent researches in his special chosen field. In Russia proper the training in economics is given in the Institute of Economic Research, the first half of the three year course being set aside for general training and the second being used for specialization in one of the fields, such as economics of industry; economics of commerce and cooperation; money and credit; public finance; international economics; and economic geography. In the Institute of Soviet Law the aspirants are prepared for the teaching of law. The special fields here are those of constitutional law, international law, criminal law and procedure, business law and civil procedure, labor law, agrarian or land law. In the Institute of History every aspirant begins in the seminar on historic materialism; in the course of his study he is supposed to work up two topics in his special field (which may be ancient history, mediaeval history, modern history, Russian history, contemporary Russian history or anthropology) and two topics in two of the other

divisions of history. In his last year of training every aspirant is supposed to teach in a university in his special field and to present to the corresponding institute a detailed outline of his course. Approximately the same study plan and the same requirements are adopted by the Institute of Red Professors, which has the following social-scientific departments: economics, with a separate sequence of agricultural courses; cooperation; history with subdivisions of western history, oriental history and Russian history; history of the Communist party; and law. The students of this institute have a four year course of study and are supposed to teach during the last two years of residence. The old Academy of Sciences also has a small number of aspirants (they are called "practicants"). A score of young scholars having the rank of junior scientific contributors are attached to the Communist Academy. The total number of persons in training for professorships and research in the social sciences is about one thousand for the entire Soviet Union.

As already indicated, at least half of the period of preparation for university teaching is devoted to research. It is not surprising, then, that the scientific output of the schools for professorial training is quite large. The total number of published titles credited to the students of the Institute of Red Professors reaches 3000, including 800 separate books and pamphlets. The institutes of Soviet Law, of Economic Research and of History form together the Russian Association for Research in the Social Sciences. This association, although it was organized only in 1923, has already published a considerable number of works.

Organized research in the social sciences is not limited to institutions designed primarily for the training of university personnel. At the present time there are in Russia a large number of organizations giving their entire time to research. Of these the principal one is the Communist Academy established in 1918 as the Socialist Academy of the Social Sciences. It is now a vast congeries of scientific institutes and learned societies, of which the following are specifically social-scientific: the Agrarian Institute, the Institute of International Economics and Politics, the Institute of Soviet Organization, the Society of Historians-Marxists and the Society of Statisticians-Marxists. In addition the Communist Academy has sections of economics and of law and government and

issues a number of periodic and non-periodic publications. The *Viestnik Kommunisticheskoy Akademii* (Herald of the Communist Academy), serving the interests of the organization as a whole, is a magazine with a file at present of thirty issues; it prints articles dealing with methodological problems. *Na Agrarnom Fronte* (On the Agrarian Front), *Mirovoe Khoziastvo i Mirovaia Politika* (International Economics and Politics), *Vlast Sovietov* (Soviet Authority), *Istoriik Marksist* (Historian Marxist), *Voprossi Ekonomiki* (Problems of Economics), *Revolutsia Prava* (Revolution of Law), are magazines serving as outlets for the respective institutes, societies and sections. Organizations for general social-scientific research outside of Moscow include the Institute of Marxism at Kharkov and the Leningrad Institute for the Study of the History and Theory of Marxism. The Ukrainian Academy of Sciences in Kiev has a special chair of Marxism and Leninism; and the White Russian Academy of Sciences also devotes a great deal of attention to the history and economics of White Russia. According to the last draft of its charter (1927), even the old Academy of Sciences in Leningrad devotes considerable attention to the whole range of the social sciences, not limiting itself to history, as it did before the revolution. After the new elections (1929) four economists joined its ranks, which contain now eleven historians but as yet no jurists. This list must be supplemented by the inclusion of two very large special organizations: the Marx-Engels Institute, with enormous archives and the largest library on Marxism in existence, which publishes the results of its researches in *Arkhiiv Marksa i Engelsa* (The Magazine of Marx and Engels) and in *Lietopis Marksizma* (Annals of Marxism); and the Lenin Institute which has extensive archives and a library and is engaged in publishing Lenin's works and correspondence.

The study of the social sciences in Soviet Russia in all research organizations and in schools of all types is based on a single scientific method, that of dialectic materialism. Only a few establishments (including until recently the Academy of Sciences) and a few of the scientists of the old school fail to reflect in their work the influence of this method. Practically all young scholars are Marxists. In the last few years, with the complete strengthening of the economic foundations of the Soviet Union, all traces of wavering in this respect have disappeared. Simultaneously with the establishment

of the Marxian method there has occurred a significant change in the subject matter studied. In the field of law, for instance, abstract investigations in Roman law and other subjects having little relevance to legislative practise of the day predominated in the pre-revolutionary period. At present organizations for the study of law function as laboratories out of which come the fundamental principles of Soviet legislation. The codes of civil and criminal law with all their later modifications are based on a long reworking of the corresponding topics in the Institute of Soviet Law and the section of law and government of the Communist Academy. The new land code was turned over for preliminary discussion to this academy by special resolution of the government. The work of economic research agencies is very closely connected with the administration of national economy. Each of the government bureaus charged with the management of the economic affairs of the country has research divisions (the Supreme Council of National Economy has a score of them) furnishing the scientific basis for its work. An overwhelming majority of economic research projects are therefore an outgrowth of the current problems of economic management (reconstruction, balanced economic development, tempo of economic development, rationalization, etc.). Other investigations attempt to summarize the changes introduced by the revolution into economic institutions and to provide a theoretical analysis of these changes. Of this nature is the work of the Commission for the Study of the Consequences of the Agrarian Revolution, attached to the Communist Academy, and the work of individual scholars, such as the book of N. I. Bukharin on the economics of the transition period (*Ekonomika Perekhodnogo Perioda*, Moscow 1920, tr. into German as *Oekonomik der Transformationsperiode*, Hamburg 1922) or that of L. Kritsman on the economics of military communism (*Geroicheskiy Period Velikoy Russkoy Revolyutsii*—The Heroic Period of the Great Russian Revolution—2nd ed. Moscow 1926). In the field of history, ancient and mediaeval history have lost ground in comparison with modern history. Instead of discussing the origin of serfdom or the character of the authority of the feudal lords in old Russia, scholars inquire now into the nature of Russian imperialism and the causes of the World War. Analogously in European history, instead of the interest in the mediaeval village, a subject

carefully studied by the students of Vinogradoff, may be observed the emergence of an interest in the party conflicts of the French Revolution or in the Paris Commune of 1871 (the works of Lukin and his students). This does not mean, however, that the general study of Russian history or of world history is entirely neglected. On the contrary, a whole range of problems could be scientifically posited and widely discussed only in Soviet Russia. Such are questions of the origin of religion, of the personality of Christ and the origin of Christianity, of the class struggle in antiquity. At the same time young Marxist scholars carefully study the works of their bourgeois predecessors. Among the books published by the Institute of Red Professors there is a large group presenting a detailed analysis of the views of various Russian historians beginning with the first half of the nineteenth century. No such aid to the study of Russian historiography was available in pre-revolutionary Russia.

From the social sciences the method of dialectic materialism is being taken over with some success into adjoining fields. Especially brilliant applications of this method have been made in linguistics. The newest theory of the origin and development of languages, put forward by the academician Marr and his school, is essentially a Marxist theory, even though Marr arrived at his conclusions, independently of any theoretical assumptions, by observation of the actual development of various tongues,

primarily those of the Caucasian tribes. In ethnology and ethnography Professor Tan (Bogoraz) is close to the materialistic school, although he is farther from Marxism than Marr. Yet Tan has many students who are consistent Marxists, so that the appearance of a Marxist school of ethnologists can be expected in the near future. Finally, in the last few years dialectic materialism has exerted a decisive influence on the study of natural sciences; the problem of a dialectic of nature is of the greatest interest to young biologists, chemists and physicists in Soviet Russia.

VII

Scandinavia

In Denmark, Norway and Sweden the universities take the lead in promoting the social sciences, both on the teaching side and in the work of research. There are state universities, with complete curricula, in Copenhagen, in Oslo and in the Swedish cities Lund and Uppsala. There are also, in Sweden, two private universities located at Stockholm and Gothenburg. The University of Gothenburg is incomplete in that it teaches only the humanities. Most of the social sciences are taught in all of these universities.

The first chair of economics in Scandinavia was founded in 1740 in the University of Uppsala and was known officially as *jurisprudentiae, oeconomiae et commerciorum professio*. One of the first persons to occupy this chair, P. N. Christiernin, was the author of some remarkable work in monetary and foreign exchange theory around 1760, anticipating parts of contemporary and later doctrines in English political economy.

Copenhagen obtained a chair of *Kameralwissenschaft* in 1785, from which economics was taught. In Oslo a chair of land economics, political science and technology was established in connection with the faculty of philosophy in 1814. Three decades later it was transferred to the faculty of law, where it was occupied by A. M. Schweigaard, a brilliant writer on monetary and tariff problems. In the last few decades there has been a tendency to free economics from its traditionally intimate connection with law. However, in Uppsala, Lund and Oslo the chairs of economics still belong to the faculties of law. In the two former universities they cover the subjects of economics and financial law; in Oslo the chair combines instruction in economics and statistics. The universities in Copenhagen and Stockholm have faculties of law and political science. The chairs of economics belong to the political science section in Copenhagen and to both sections in Stockholm, where there is also a chair of economics in the humanities faculty. In Gothenburg economics is associated with the humanities.

The university colleges of commerce in Stockholm and Gothenburg, and the University College of Technology of Trondhjem (Norway), all of undoubted university standing, also have professors of economics.

The number of chairs with or without such additional subjects as statistics or financial law is eight in Sweden, four in Denmark and three in Norway. In addition there are a number of assistant professors (*docents*) and lecturers in the institutions already mentioned and in special institutes for higher studies of technical subjects, forest problems, etc.

In Sweden political science has long attracted a great deal of attention. As far back as three hundred years ago the University of Uppsala established a chair of political science and rhetoric in connection with its faculty of philosophy, and later the universities of Lund and Gothenburg established chairs of political science. The three law faculties have chairs of constitutional law and devote special attention to the legal aspects of political science. Similar chairs exist in the universities of Copenhagen and Oslo.

Sociology has been rather neglected in Scandinavia. Nowhere is there a chair exclusively devoted to this science. Gothenburg University has a professorship of economics and sociology. From 1883 to 1918 Copenhagen University had one dealing with philosophy and sociology. At present the teaching in sociology is done by one of the professors of economics.

In Lund and Uppsala sociology has been classed as a branch of practical philosophy. Some of the professors have lectured and written on sociological topics in the speculative and abstract manner which dominated sociological science everywhere in the last century. Newer tendencies of sociological thought of a more concrete sort have hardly become known to Swedish students, except in Gothenburg.

Among other sciences treated in a way that makes them akin to the social sciences history should be mentioned first of all. Particularly in the last two decades leading historians have

begun to place emphasis on economic and sociological factors. This tendency, which is a reaction against excessive concentration on the purely political aspects of history, is perhaps more conspicuous in Norway than in Denmark and Sweden. But in all three countries economists and historians have become aware of the necessity of cooperation in the treatment of subjects which border on their respective sciences.

The law faculties in all the Scandinavian universities with complete curricula have long had chairs of legal history and public law. The treatment of these subjects by the different professors has been varied. In some cases the sociological viewpoint has played a prominent part and it tends more and more to come to the fore. The same tendency can be found in the treatment of other branches of the legal sciences.

Recently some professors of psychology have dealt with the social aspects of their subject. The economic aspects of geography have been given increasing prominence. Anthropology is not taught in Scandinavian universities, except in connection with anatomy, archaeology and ethnology. Students of the two latter sciences naturally acquire some contact with the social and sociological viewpoint.

Ever since 1848 the University of Copenhagen has had a special degree for the students of social sciences, *candidatus politicus*. In general five and a half years of study are required, which corresponds to an American post-graduate course of about three years. Economics is the principal subject studied, but statistics, sociology, economic history, public law, constitutional law and other subjects are also included. The University of Oslo has a similar examination in economics and statistics, but its preparation takes only half as long. In Sweden the social sciences can be combined with any other subject taught in the philosophy or humanities departments. The law students in all three countries study a little economics. In the university colleges of commerce economics, economic geography and statistics naturally play a large part.

The teaching used to be done by means of lectures, sometimes supplemented by the discussion of papers in seminars after the German pattern. In late years discussions and laboratory work have come to play a more important part. Nevertheless the "case method" has not had much influence on the mode of teaching. Absolute freedom of teaching is an old tradition

in Scandinavian universities and is jealously guarded. There is no danger that a scientist's views, whether radical, communistic or of any other tendency, will furnish the occasion or the pretext for preventing him from teaching.

Various social sciences are taught outside of the universities. In Sweden this kind of instruction is given at the Institute of Social Policy and Municipal Government, the Citizens' School and the Workers' Institute. Folk high schools in the country districts and circles of study under the direction of scientists in the four university towns should also be mentioned. In Denmark the Teachers' High School, the Workers' High School and various folk high schools give elementary courses in social sciences. The Folk University Association also arranges series of lectures on social subjects. In Norway there are folk academies and workers' institutes. The Nobel Institute in Oslo has recently appointed a couple of lecturers on the social sciences.

In all three countries the business schools teach elementary economics, and the higher ordinary schools and seminaries for primary school teachers give some instruction in "knowledge of society." A number of associations of present or former students of the social sciences arrange lectures and discussions. These associations are separately organized in connection with each science, such as economics, political science, etc. In Sweden the Academy of Sciences has a special economics section, and in Norway the Academy of Sciences has a section devoted to the legal and social sciences. In Denmark social scientists are not represented in the corresponding institution, which includes only a limited number of the "older" sciences.

The foundations which exclusively support research in the social sciences, e.g. the Fahlbeck Foundation at Lund, and the Aschehoug Foundation in Oslo, are small. Foundations for the advancement of scientific work in general are of course numerous, but some of the largest concentrate on subjects other than the social sciences. A notable exception is the Carlsberg Foundation in Copenhagen which has given large amounts to promote research in economic and social history. It also supports the Institute of Economics and History which, aided by grants from the Laura Spelman Rockefeller and the Rask-Ørsted foundations, carries on research and teaching in connection with economics and economic and social history. The Commodity Insurance Foundation in Oslo gives

considerable amounts for research in economics.

The university and the University College of Commerce in Stockholm have joined in creating the Institute of Economic History. The Institute of Social Sciences is a part of the same university, and has received a grant from the Laura Spelman Rockefeller Foundation to be used in an intensive study of wage problems.

It is not difficult for young scientists to obtain grants from various foundations for defraying at least a part of the cost of printing their works. On the other hand scholarships for students of the social sciences abroad are rare, particularly in Denmark.

Among the publications devoted to the social sciences should be mentioned those edited by the Fahlbeck Foundation in Lund and by the economic section of the Academy of Science in Stockholm, both in Swedish, and the series published in English by the Stockholm Institute of Social Sciences. The most important scientific journals are: *Ekonomisk Tidskrift* (Uppsala), *Statsvetenskaplig Tidskrift* (Lund), *National-ökonomisk Tidskrift* (Copenhagen), *Statsökonomisk Tidskrift* (Oslo) and *Nordisk Statistisk Tidskrift* (Stockholm). In each country a government department dealing with social affairs publishes a monthly or bi-weekly journal, which sometimes contains articles of scientific interest. Historical and legal periodicals which include

articles of interest to students of the social sciences are numerous.

Before the war the place of the social sciences in Scandinavian culture was rather insignificant. Undoubtedly, however, the cultural influence of the social sciences is growing rapidly. Their point of view is permeating all related sciences. In this way students of history, archaeology, ethnology, psychology and law come into contact with the social science viewpoint. The average "educated" man or woman is forced to give much more attention to the subject matter of the social sciences than was the case a generation ago. Economics, in particular, is growing in importance. This is partly a result of the war and the post-war crisis, which raised so many economic problems. It is partly due, however, to the energetic work carried on through small books and newspaper articles by Scandinavian economists in behalf of the "popularization" of economics.

The social sciences have not yet come to be regarded as a unit or natural group, a fact which may have something to do with the neglect of the most comprehensive of them all, sociology. As interest in sociology is lively among students in every branch of the social sciences, efforts to remedy the existing state of affairs will probably be successful within a short time.

BERTIL OHLIN

VIII

Spain and Portugal

It would be difficult to say precisely when the social sciences became the subject of scientific study in Spain. Mediaeval philosophic thought differed considerably from the social sciences in the modern sense. It was complicated by its threefold division into the Jewish-Spanish, Hispanic-Arabic and Christian strains, by the vastness of the subjects which it treated, and by the intellectual boldness with which they were attacked. An arbitrary starting point can be made in the sixteenth century, the decisive moment in the European cultural renaissance.

The outstanding work of that time was done, as was natural from the institutional character of the period, in the field of ecclesiastical and political theory and law, and in colonial history and geography. We may mention first the works of Juan Luis Vives, *De subventionem pauperum sive de humanis necessitatibus, libri ii* (Burgos 1526, tr. by M. M. Sherwood, New York 1917), and *De causis corruptarum artium* (Burgos 1531); *De rege et regis institutione* (Toledo 1599) of the famous Jesuit Mariana, which made such a marked impression on the theories of the monarchomachs; and the work which is now attracting the attention of internationalists, the *Relectiones* (Lyons 1557) by Francisco de Vitoria, professor in the University of Salamanca, an advocate of theological and legal reform. The social significance of Vitoria's contribution to the study of international problems eluded the appreciation of most of his contemporaries. As the first quarter of the seventeenth century was drawing to a close, Francisco Suarez published his *De legibus ac deo legislatore* (Antwerp 1613), which unequivocally proclaimed the doctrine of the solidarity of nations—the *mutua juvamine*—or the necessity of mutual support as the basis of international law. It has been disputed whether Vitoria or Suarez was responsible for the doctrine; Lange and Barthélemy credit Suarez, while James Brown Scott believes that Vitoria was the real creator of the idea. Historians of the West Indies also made valuable studies on the social conditions of the American aborigines which formed a basis for the more accurate work which followed.

Especially important in this respect is the notable *Historia general y natural de las Indias* (Seville 1535-37) by Gonzalo Fernández de Oviedo y Valdés; the *Historia verdadera de la conquista de Nueva España* (first published Madrid 1632) written by Bernal Diaz del Castillo, a soldier who served under Cortes; and in addition the works published by Augustin de Zarate, Pedro de Cieza de León and Alvar Núñez Cabeza de Vaca, to cite only the most famous among these early writers. The geographers in their turn revealed new horizons in what is now called human geography, as was recognized by Pietro Martire d'Anghiera, a Milanese chaplain to the crown of Castile, in his *De orbe novo* (Alcalá de Henares 1530) and by the less known cosmographer of the Indies, Juan López de Velasco, who wrote the excellent *Geografía y descripción universal de las Indias* (1574, first published Madrid 1894) including a census, a description of the settlements, a study of customs and of Spanish colonization in general. A similar document for the English colonies is not found until the time of Chalmers.

But the general impoverishment of Spain and its political decadence could not fail to influence national thought. In the sixteenth century under Charles V and Philip II, for religious as well as for economic reasons, a decided drift set in toward the "closed economic state." In fact the mercantilist tradition, as Schmoller has pointed out, was a growth of great antiquity in Spain, dating probably from the end of the reign of James I of Aragon in the fourteenth century. As national depression reached its maximum in the course of the seventeenth century, men appeared who gave voice to the national needs and formulated programs of economic reform in mercantilistic terms. This literature began with the *Restauración política de España* (Madrid 1619, reprinted 1746) of Sancho de Moncada, and continued down to the nineteenth century. Moncada favored an anti-export law for raw materials and metals in order to stimulate the industry of the country. Later Francisco Martínez de Mata published his *Memorial en razón de la despoblación*

ción, pobreza de España y su remedio (n. p. 1650), reprinted by P. R. de Campomanes in his *Apendice a la educación popular* (4 vols. Madrid 1775-77); in this work the problem centers more on protection and other means of encouraging manufactures, as the only way to produce wealth and bring about an increase of population. Meanwhile the economic-political decadence continued and when the house of Austria was superseded by the house of Bourbon (1701), the regeneration of the exhausted country was no longer merely a matter of academic discussion but the compulsory text for all thinkers. The man who knew how to give scientific form to the convictions of the cultured men of the time was Jeronimo de Uztariz, who marks the culmination of Spanish mercantilism. His famous *Teórica y práctica de comercio y de marina* appeared in 1724 in Madrid and spread rapidly through Europe; an English translation appeared as early as 1751 and a French translation by Forbonnais in 1753. His plea for "well protected and better regulated commerce" enjoyed the support of such statesmen as Patino, adviser to Philip V, who mentioned it in the memoir which he presented to the king in 1726.

The general national renaissance in industry and science under Charles III (1759-88) had particularly important consequences for the social sciences. In that period university studies were reformed and the modern viewpoint was introduced into the teaching of philosophy and law (which included the study of political economy). However, the reform of the economic and related disciplines did not take place in the universities, but outside them, in the Sociedades Económicas de Amigos del País founded in all the provinces of the peninsula as well as overseas. These societies promoted research, held prize contests for the best pieces of writing and by means of their publications spread throughout the country an interest in financial, commercial, industrial and agricultural problems. Although the societies still exist they have deteriorated during the past century; however, they still have valuable libraries which are open to the public and records which are of the greatest importance. These records, especially the publications of the Sociedad Económica Matritense (*Memorias*, 5 vols. 1780-95; *Anales*, 3 vols. 1852-54), are equaled by no other scientific source material in the light they shed on the situation in Spain and its colonies at the end of the eighteenth and the beginning of the nineteenth century.

The progress of Spain in the eighteenth century and the liberal movement symbolized by Charles III were interrupted, the latter by the fear which the French Revolution inspired, and the former by the Napoleonic invasion, the general uprising and the internecine wars in which Spain was involved for five years. Business was ruined. The constitutional regime which was established in 1810 attempted to reorganize the national administration, but was handicapped by the vicissitudes which beset it until its fall in 1834. Yet the social sciences did not cease to be an object of study. In 1794 the first translation of Adam Smith's *Wealth of Nations* had been made by A. Ortiz. Even though it was proscribed by the Inquisition on grounds of "low style and moral license," that did not affect its spread inside and outside the universities. In fact the proscription had earlier been an incentive to its diffusion, especially after the first years of the French Revolution had passed and the Inquisition had been weakened never to be restored, dying legally in the Cortes of Cadiz in 1810. The renown of Adam Smith was later shared by J. B. Say, the works of both enjoying the character of recognized texts.

This second period, which includes the eighteenth century and the beginning of the nineteenth, was marked by constructive programs and achievements in public affairs and by development in the social sciences. It was the period that began with the census of the Marqués de la Ensenada in 1748 and ended with the census of de la Riqueza of 1800, directed, it seems, by Campomanes. This period witnessed the projects of Campillo for the economic-commercial reorganization of Spain and its colonies, the founding of the San Carlos bank, the writings of Forner and Salazar on the political and economic reconstruction of Spain, and the publication of the voluminous work *Origen, progresos y estado de las rentas de la corona* (7 vols. Madrid 1805-08) of F. Gallardo y Fernandez, giving a history of taxes in force at the beginning of the nineteenth century and outlining the administrative organization of the treasury. It was a period further distinguished by the work of Aranda, Floridablanca, Cabarus, Jovellanos and Canga-Arguelles. In the period that followed—the first half of the nineteenth century—the chief economists were A. Florez Estrada, the author, among other works, of a *Curso de economía política* (first edition in London, 1828, the seventh and last edition in Oviedo, 1852; translated into French by Gali-

bert, París 1833) and Ramón de la Sagra, whose *Lecciones de economía sociala* were published in Madrid in 1840. Estrada was praised by Blanqui in his *Histoire de l'économie politique* (2 vols. París 1837, vol. ii, p. 300-02) while an interesting study of Sagra was written by Viscount Alban de Villeneuve-Bargemont in the *Journal des économistes* (vol. vii, 1844, 358-80). Both Estrada and Sagra are again being studied by the new generation of scholars. The first commercial code in Spain was published by Pedro Sainz de Andino in 1829, and in 1830 ex-Minister F. J. de Burgos delivered some *Lecciones de administración* in the Liceo of Granada, which form the basis of the subsequent development of the theory of public administration.

Two events must be stressed as fundamental in the present position of the social sciences in Spain: the Revolution of 1868 and the Spanish-American War of 1898. The first of these had as one of its antecedents the great university dispute which arose in 1866. The government representing the greatest power reached by the ultramontane forces, supported by Rome and by similar strong groups in Austria and France, demanded, because of political reasons in which it was deeply involved, a special oath of allegiance to the queen and to the official religion. The concordat between Spain and the Holy See, which was signed in 1851, had granted to the church the right to supervise instruction and gave a semblance of legality to the act of the government, although actually the arrangement was never put into practice in the university centers. A group of professors refusing to do what the government required resigned their posts only to resume them when the Revolution of 1868 proclaimed the principle of absolute academic freedom. From 1868 to 1876 the University of Madrid was the center of reform which found expression in liberal courses and in the university organ *Revista* (1869-77). In 1876 the monarchical restoration again raised the question that had been raised a decade earlier, although the government now asked only for inspection of the curricula in order to preserve purity of doctrine. A still greater number of professors refused. They were expelled and in 1876, under the leadership of Francisco Giner, founded the Institución Libre de Enseñanza, which is still in existence and which was the home of the Spanish intellectual revolution. Although this institution started as a liberal university, it later became a primary and a secondary school, the leader in pedagogical reform, and an advocate

of coeducation and of religious neutrality. Its influence in the country has been enormous.

In 1881 the government receded from its position of 1876 and thenceforward the Spanish professor enjoyed as complete academic freedom as his English colleague. In Spanish universities today, professors in conflict with such institutions as the monarchy, the Catholic religion (and concretely with the church) and the capitalistic property system, are not as a rule hampered in their activities. But this struggle stimulated the doctrinal polarization of the social sciences in Spain, giving rise to what may be considered the two schools of Spanish thought around which the names of the principal social scientists may be grouped. On the one hand the traditional Catholic school was revived with the sap of Christian socialism and gave place in our day to Christian democracy with its well-known influence on the life and legislation of the country. In this group the profound ideas of Donoso Cortes, the most celebrated of the Spanish ultramontanes, have ceased to hold sway and have been superseded by the social doctrines of Leo XIII; representative of this trend are Sanz y Escartin, Aznar y Embid, Sangro y Ros de Olano, Burgos Mazo and Ruiz del Castillo. On the other hand the liberal spirit of the Revolution of 1868 has descended upon the school that upholds the doctrine of the social organism as an ethical entity. The doctrine was inspired by German idealism, especially by Krause, and expounded and spread by Julian Sanz del Rio, professor at the University of Madrid. The real founder of this school was Francisco Giner de los Rios, professor at the University of Madrid, who founded the Institución Libre. He was the author of works on Spencer, Schäffle and Wundt which widely attracted the attention of scholars. His individual viewpoint appears most clearly in the *Resumen de filosofía del derecho* (Madrid 1898), *La persona social; estudios y fragmentos* (Madrid 1899), and in the work presented at the International Congress of Sociology in 1898, *La ciencia como función social*. Giner left a profound impression upon Altamira, Costa, Dorado Montero, Buylla, Bernaldo de Quirós and Posada. Positivism also found representatives in Sales and Ferrer (*Tratado de sociología* 1897) and the criminologist Salillas.

The defeat in the war with the United States in 1898 and the resulting loss of the last possessions of Spain in America had a cathartic or purifying effect on Spanish social thought. As

a result of the war there arose a historical literature in which the past and present were frankly analyzed; and extra-university institutions were created to cope with the pressing social problems. The new doctrines began to be discussed and new points of view put forward in the Ateneo Científico y Literario y Artístico at Madrid. Likewise the Real Academia de Ciencias Morales y Políticas took part in the new movement. It not only held discussions but organized scientific competitions, offering generous financial awards for the best monographs. As has happened at other times, the universities took no active part in developing the new social disciplines and comparatively little is being done there even at present. Sociology is represented by only one chair in the faculty of philosophy in the University of Madrid and by another one on "social policy" under the faculty of law. Under these faculties social studies are being made in connection with Roman law, politics, and commercial, administrative, criminal and international law. The study of economics and finance is also supervised by these faculties. Studies in anthropology, prehistory, ancient and mediaeval history are carried on under the faculties of history and science. Recently a new chair of municipal law was established, which is held by the scholar Posada.

In the Museo Pedagógico Nacional, officially established in Madrid in 1885-86, a corps of technicians, working until February, 1929, under the direction of Manuel B. Cossio, later professor of pedagogy in the University of Madrid, have effected fundamental pedagogic reforms involving the teacher, the school building, the methods of teaching the various disciplines and of maintaining contacts between the schools and their graduates and the graduates' families. The museum's investigations range from the study of the teaching problems in foreign countries or of some individual concrete subject to a survey of the condition of schools in Spain. Its publications are distributed free of charge.

But it was after 1898, after the campaign of Costa y Martínez in his *Reconstitución y europeización de España* (Madrid 1900) and after the appearance of such of Giner's works as the *Problemas urgentes de nuestra educación nacional*, that the country's reaction really set in. In the first years of this century (1903-04), the state founded the Instituto de Reformas Sociales for the purpose of investigating social problems. It was self-governing under a board of directors, and was divided into sections of which the prin-

cipal ones were those for industrial technology, statistics, economics and legislation. There Christian democrats like Sanz y Escartín and Burgos Mazo collaborated in the same enterprise with Azcarate, Buylla and Posada, who might be called socialists of the chair, and soon even Marxian socialists joined the governing board. The institute made various studies of the problems confronting Spain, as a means of showing the application of their doctrines to objective situations. A monthly organ, *Boletín del instituto de reformas sociales* (1904-24), published the results of this work and additional monographs by specialists on such subjects as strikes, agricultural questions and labor contracts. In 1924 the institute lost its autonomous character and was incorporated in the labor ministry as a labor council. From its ashes and through the influence of one of its best specialists, Leopoldo Palacios, arose the Escuela Social, organized by the ministry itself. Its classes are attended chiefly by especially qualified workers, employers and ministry employees; its curriculum includes cultural history, social economics, industrial legislation, law, industrial technology and economic and human geography, in addition to modern languages and stenography. The labor ministry publishes the *Revista de política social* which deals not only with departmental activities but also with theoretical problems. The General Statistical Bureau under this same ministry publishes the *Boletín de estadística* (1918-) and the *Anuario* (1858-) furnishing statistical data on the economic and social life of the country.

The Instituto Nacional de Previsión, which was organized as a branch of the institute mentioned above, also independent of the labor ministry, deals with all problems relating to the establishment and administration of social insurance schemes. For instance, it has recently assisted in preparing a program of maternity insurance. Research in the institute is carried on by engineers, practical technicians and university professors; the administrative personnel is given special training at the institute. The Universidad Industrial of Barcelona also deserves mention in this connection, although it concentrates on the practical application of the results of its scientific research.

Investigations in the newer social sciences are conducted by members of the professorial ranks in centers that owe their origin, for the most part, to the Junta para Ampliación de Estudios é Investigaciones Científicas, founded by the state in 1907. This institution is the sig-

nificant instrument of reform in Spanish cultural life. It is autonomous, and sends students and professors to foreign countries in order to form international contacts. Upon their return they organize in groups called "research centers." In the research center which has been established by the historians and jurists, the new aspects of social history are receiving attention. This emphasis had previously appeared in such works as the *Historia de las instituciones sociales de la España goda* (4 vols., Valencia 1896) by E. Pérez Pujol; *El colectivismo agrario en España* (Madrid 1897) by J. Costa y Martínez; *El régimen señorial y la cuestión agraria en Cataluña durante la edad media* (Madrid 1906) and the valuable study *El elemento germánico en el derecho español* (Madrid 1915) by E. de Hinojosa de Naveros; *La enseñanza de la historia* (2nd ed. Madrid 1895) and the *Historia de España y de la civilización española* (4 vols., Barcelona 1900-11) by R. Altamira y Crevea, the only living member of this reform group. The group of historians and jurists who work within this institution publish the *Anales para la historia del derecho español*. The title gives an imperfect idea of the contents, for it includes profound studies on the history of Spanish economics and on social and legal institutions. Assiduous contributors to those annals are Sánchez Albornoz, Carando, Díez Canseco and Ots Capdequí, already real masters in their own fields. Unfortunately the Arabists have no organ in which to publish the results of their research on Hispanic-Arabic culture and there is no index to their writings. However, a useful bibliography accompanies the recent book by Professor C. A. González Palencia, *Historia de la España musulmana* (Barcelona 1925). The most significant contributions to the study of Hispanic-Arabic culture are the studies on the administration of justice and of teaching under the caliphate by Ribera Tarrago, the writings of M. Asín Palacios on the history of the Mussulmanic religions, and the work of Lafuente Alcántara, González Palencia and García Gómez on related topics.

Work in the anthropological and related sciences is being done in the Centro de Estudios Históricos of Madrid and at the Institut d'Estudios Cataláns of Barcelona. Palaeontologists and ethnologists jointly are publishing the newest works on Spanish prehistory. The archaeologists such as Professors Obermaier, Hernandez Pacheco and Gomez Moreno are making valuable contributions by the study of art as a social

phenomenon and as the expression of the cultural situation. The philologists under the great master Ramón Menéndez Pidal are making distinguished contributions to Romanic culture, throwing light on literary myths and analyzing the influences playing on the formation and degeneration of a language. In this group Professors Onís, Americo Castro, Navarro Tomas and Damaso Alonso are important.

Economics has been cultivated by writers like Borrego and professors like Conte, Colmeiro and Piernas Hurtado. The writings of Antonio Flores de Lemus, professor at the University of Madrid, symbolize the change which the study of economics has undergone by incorporating mathematical statistics. His works on the tariff, his unsigned essay on the abolition of consumption taxes in Spain, the plan for local taxation which he elaborated and published and which became the basis of the laws that reconstituted the local treasuries, another unsigned treatise, *Dirección general de contribuciones*, on administrative defects in tax collection, make him the recognized authority in these disciplines. His position as technical assessor in the ministry of finance converts that office into a real research center which is frequented by students and professors studying methodological problems in economics, mathematical statistics and finance. At present Flores de Lemus, assisted by his pupil Professor Viñuales has—at the government's request—proposed a plan for putting the Spanish currency on the gold standard basis. The Spanish banking association is already under the technical direction of an eminent Spanish economist, Bernis, formerly professor of the University of Salamanca, and author of many valuable works.

Political science is the object of special attention in non-university circles. The Escuela de Criminología, an official institution founded at almost the same time as the Junta de Ampliación de Estudios, has as its principal purpose the training of personnel for the handling of prisoners. The subjects to which it devotes particular attention are criminal sociology, corrective pedagogy, anthropology and physiological psychology. This institution was headed until his recent death by the penologist Rafael Salillas, author of *El delincuente español* (2 vols., Madrid 1896-98). International affairs have become a subject of study by organizations such as the Asociación para el Estudio del Derecho Internacional, the Asociación Francisco de Vitoria and the Seminario de Estudios

Internacionales, which has begun to publish a *Boletín de información internacional*. The schools of engineering and architecture are manifesting great interest in economics, contributing to the solution of the problems of scientific management. The Centro de Orientación Profesional, recently established by the state, is also studying questions of personnel management.

In Portugal the position of the social sciences in the universities is similar to that in Spain. The curriculum of the law faculties is with slight variations the same as in Spain and thus includes among other subjects economics, political science, finance and commercial law. In 1902 the University of Coimbra was reorganized and a chair of sociology established. However, the revolution that overthrew the monarchy did not expand the scope of the social sciences. But Portugal has had eminent historians and sociologists such as the great Herculano, an

extraordinary mediaeval scholar who continues to exercise great influence, and Gama Barros, historian of administration in the Middle Ages and himself an innovator in this field in our own day. The greatest historian and sociologist on the peninsula is the Portuguese, J. P. Oliveira Martins, whose *Historia da civilisação ibérica* (Lisbon 1879) is being continually reprinted in Portuguese and Spanish. Oliveira's anthropological works, *Quadro das instituições primitivas* (2nd ed. Lisbon 1893) and the *Systema dos mythos religiosos* (Lisbon 1882), are both of the highest order. In 1919 a decree was promulgated establishing the Instituto de Seguros Sociales which, like its counterpart in Spain, was to stimulate scientific investigation, but it has not begun to function. At present the younger scholars, whose organ is the review *Sara nova*, are taking a lively interest in the problems of social science.

FERNANDO DE LOS RIOS

IX

Latin America

The twenty Latin American republics conform essentially to the same cultural pattern in the matter of the social disciplines and may be considered together. Individual differences, due to variations in cultural development or in local needs, will be noted. The development of the social sciences in Latin America falls into three well marked periods.

I. THE COLONIAL PERIOD. The first generation of the Spanish conquest was devoted to the economic and religious exploitation of the Indians by the conquistadores, the priests and brotherhoods. As a consequence no literature of note was produced in the first generation by the invaders, and the already fairly well developed literatures of Mexico, Yucatan and Peru were practically destroyed. One priest and pacifier, Landa, boasted of having destroyed twenty-seven Maya manuscripts at one burning. The succeeding generations, however, brought forth several types of literature dealing with social subjects. Some of the more liberal spirits attempted to recover what they could of the rapidly vanishing indigenous civilizations. Fernando de Alva Ixtlilxochitl, a mestizo, descendant of the ancient kings of Texcuco, was able to make the largest contribution to this work because of his knowledge of the Indian tongues and his access to the confidence of the surviving literati. He translated some of the old manuscripts which had escaped the priestly ravages, due to the fear of the magic that both Indian and Spaniard supposed them to contain, and he also wrote several historical and anthropo-archaeological treatises on the indigenes. The best of these was *La historia chichimeca*. Many of the clergy and conquerors also included much material of an archaeological character in their early historical narratives.

These historical works fall into two classes: those written by the Spanish adventurers in their old age, recounting the exploits of the conquest, and more formal histories produced usually by the clergy with the intention of giving to Europeans and Americans comprehensive accounts of the history of the new

world, or portions of it, in as much detail as was possible from the limited resources at their disposal. Perhaps among the best known of the former class were the *Historia verdadera de la conquista de la Nueva España* (Madrid 1632) of Bernal Díaz del Castillo (died 1560) and Juan de Castellanos' *Historia del nuevo reino de Granada* and *Elegías de varones ilustres de Indias* (Madrid 1589). Histories of the second type were relatively numerous and they were more definitely a Latin American product. These histories began to appear by the middle of the sixteenth century and continued throughout the colonial period. The more important of these works naturally appeared in the older portions of Latin America, some of them being printed in America and others in Spain. Among these early histories dealing with Mexico or New Spain were Fray Toribio de Motolinia's (died 1569) *Historia de los indios de Nueva España* (about 1536-41), generally regarded as the best review of the work of the conquerors and missionaries in Mexico, and Juan de Torquemada's *Monarquía indiana* (Seville 1615), a general account of political and ecclesiastical affairs in Mexico in the sixteenth century drawn in part from the preceding author and from Mendieta. To these should be added Bartolomé de las Casas' (1474-1566) *Brevísima relación de la destrucción de las Indias* (Seville 1552), and two large manuscript works, including an *Apologética historia sumaria quanto á las calidades, disposición, descripción, cielo y suelo de estas tierras; y condiciones naturales, políticas, repúblicas, maneras de vivir y costumbres de estas gentes de las Indias occidentales y meridionales, cuyo imperio soberano pertenece á los reyes de Castilla*, written to prove that the Indians were not savages before the coming of the Spaniards and therefore without civil and moral rights according to the contemporaneous theories of the rights of savages, and a large three-volume manuscript *Historia general de las Indias*, covering the period between 1492 and 1520. These works are among the greatest fulminations against greed and injustice in the service of power of all times. Antonio de Her-

rera y Tordesillas' *Historia general* (8 vols., Madrid 1601) is one of the best sources for Indian life and customs. Fray Agustín de Betancurt's (1620-1700) *Teatro mexicano, Descripción breve de los sucesos ejemplares, históricos, políticos, militares y religiosos* (4 vols., Mexico 1697-98), *Cronografía sacra* (Mexico 1696) and *Tratado de la ciudad de México*, and Jerónimo Mendieta's (1525-1604) *Historia eclesiástica indiana* (ms. 1596, published Mexico 1870), which laid bare the crimes, vices and oppressions of the conquerors, are other standard historical and archaeological works of the period. Quito (Ecuador), which occupied a position of marked importance in Spanish colonial culture, produced some important works, including Diego Rodríguez de Ocampo's *Relación de lo que era el reino de Quito al tiempo de la conquista y de su estado presente*; Miguel Uriarte y Herrera's *Representación sobre los adelantamientos de Quito y la opulencia de España* (1757); Juan de Velasco's *Historia del reino de Quito* (1789); and Jacinto Callahuazo's *Las guerras civiles del Inca Atahualpa*, which served as basis for the preceding work.

The historical treatises produced in Peru and in Chile (which in colonial times was a part of Peru) have been numerous. Some of the most important of these works were Cristóbal de Molina's *Conquista y población del Perú* (written about 1552); Alonso de Góngora y Marjaiejo's *Historia del reino de Chile*; Alonso de Ovalle's (born 1601) *Histórica relación del reino de Chile* (Rome 1646), still an important authority; Diego de Rosales' (1605-77) *Historia general del reino de Chile* (3 vols., ms. until 1878), important for its archaeological materials, and his *Conquista espiritual del Chile*; and Miguel de Olivares' (born 1674) *Historia de la compañía de Jesús en Chile* (Santiago 1861) and *Historia militar, civil y sagrada del reino de Chile* (2 vols., begun 1736 and published Santiago 1864-1901). Two noteworthy early Peruvian historians were Pedro Cieza de León (1518-60), who wrote *Crónicas históricas del Perú y de las guerras civiles* (pt. i, Seville 1553, pt. ii, 1873) and Garcilaso de la Vega (born 1539), a mestizo, who produced *Comentarios reales*, one of the ablest books on the Indians and early Spanish events. Four early Cuban histories may be mentioned, the *Teatro histórico, jurídico, político, militar de la isla Fernandina de Cuba* (ms. 1791, Havana 1876) by Ignacio José de Urrutia (born 1730), *Historia de la isla de Cuba y en especial de la Habana* (1811) by Antonio José Valdés

(born 1752), *Relación de lo espiritual y temporal del obispado de Cuba* by Fray Alonso Enríquez de Armendáriz, and *Llave del nuevo mundo y antemural de las Indias occidentales* (ms. 1761, Havana 1830-31) by José Martín Arrate (born 1697). The works cited above represent only a few of the many histories written in the colonial period, but they will serve to indicate the types of subjects treated and the character of the writing. Composed principally by the clergy, they divide their attention primarily among the curious heathen customs of the savages, the devout labors of the missionaries, and the remarkable secular events of the country, with varying degrees of approval of the deeds of the conquerors. These narratives do not differ markedly, except perhaps in their greater number, piety, and propagandistic spirit, from those of our own colonial period.

These colonial writers were also keenly interested in geography, since nature was not always easy to deal with in tropical America and distances were great. Pedro Vicente Maldonado's (1709-48) *Mapa del reino de Quito* (Paris 1747) and *Relación del camino de Esmeraldas* and Juan Romualdo Navarro y Montesión's *Descripción geográfica, política y civil del obispado de Quito* are typical examples from colonial Ecuador.

Since practically all of the teachers in the colonial universities were priests or members of religious orders it is not surprising that there was a large theological output, taking the place to a considerable extent of what became the social sciences in the nineteenth century. Three Jesuits—José de Acosta (born 1539), Blas Valera and Alfonso de Barzena (1528-78)—published the first book to be printed in Peru, *Doctrina cristiana* (1584). This book was translated into several Indian languages for missionary purposes. Acosta also wrote a *Historia natural y moral de las Indias* (1591) and *Fasti novi orbis de procuranda indorum salute* (Salamanca 1588). Ecuador, always noted for the theological spirit of its culture, is represented by Juan Bautista Aguirre's *Tratado polémico-dogmático*, Isidoro Gallegos' *Actibus humanis* (1677), *Perfectionibus Christi*, and *Curso de filosofía*, Antonio Ramón de Moncada's *Usu et abusu scientiae mediae*, Alonso Peñafiel's *Philosophia universa* (León 1653) and *Obligaciones y excelencia de las tres órdenes militares*, Santiago, Calatrava, y Alcántara (Madrid 1643), Baltasar Pinto's *Phylosophia* (ms.) and *Animástica* (ms.), and Francisco Rodríguez

Fernández' *Segundo pecado original del paraíso de las Indias* and *Colección de sermones*. To the above should be added various social, juristic and theological treatises of Bartolomé de las Casas, written in the sixteenth century in defense of the Indians, but of universal scope as far as fundamental principles are concerned, including *Tratado comprobatorio del imperio soberano y principado universal que los reyes de Castilla y León tienen sobre las Indias* (Seville 1553), *Tratado sobre la materia de los indios que se han hecho en ellos esclavos* (Seville 1552), *Avisos y reglas para los confesores q. oyeren confesiones de los Españoles que son, ó han sido en cargo á los indios de las Indias del mar oceano* (Seville 1552), and a voluminous unpublished work, *Sobre socorrer y fomentar los indios*.

The social sciences in the restricted sense had their development primarily through the universities. The very high culture of colonial Latin America is attested by the early establishment of her numerous universities, always under the patronage of the clergy and the king. The most famous of these, with the dates of their establishment, are as follows: The University of San Marcos (Lima, Peru), 1551; Mexico, 1553; Santo Domingo, 1558; Colombia (New Granada), 1572; Córdoba (Argentina), 1614; Chuquisaca or Charcas (Bolivia), 1623; Havana (Cuba), 1728; Santiago de Chile, 1747; Quito (Ecuador), 1787; and Buenos Aires, 1821 (with predecessors going back to 1763). All of these and various other universities taught one or more phases of the law and theology, including natural law and moral philosophy, which were in Latin America as in British America the true forerunners of the social sciences proper. In the ancient University of Mexico the chairs were, from its foundation, theology, sacred Scriptures (Bible), canon or ecclesiastical law, civil law, institutions and laws, arts, rhetoric and grammar. Some years later medicine and languages (including the Mexican) were added. In the University of San Marcos (Peru) in 1576 the chairs included, with the number of courses to each subject, grammar (two), native languages (one), theology (three), laws (three), canon law (two) and medicine (two). Part of the requirement for a degree from this institution was at that time to swear to defend the mystery of the immaculate conception. In 1770 the University of San Marcos was somewhat liberalized under the enlightened reign of Carlos III of Spain, but it was not until 1861 that it became a modern university. The

other universities were organized in a manner similar to those of Mexico and Peru. They had been founded by the clergy primarily to train churchmen, particularly missionaries, and secondly to prepare men to administer the affairs of state. Most of the important government officials were, however, chosen from pure-bred Spaniards and sent out from Spain, having been previously trained at Salamanca, if they were trained at all in a university.

In the sixteenth century Spanish learning was a tradition, but in the seventeenth and eighteenth centuries, with the decline of Spain, the University of Salamanca and her American imitators became extremely conservative. This new spirit was felt particularly in law and theology. Spanish law practically ceased to be taught in the universities and the growing classicism and conservatism limited law instruction almost wholly to civil (Roman) and canon law. Also the clerical teachers in the Spanish-American universities did what they could to prevent the influx of the new ideas from Europe which began to appear about the middle of the eighteenth century. In 1767 Carlos III expelled the Jesuits from his dominions, including the American colonies, and the growing trade due to the rising commercial revolution brought in new ideas as well as more widely distributed commercial prosperity toward the end of the eighteenth century. The universities now came under the control of more liberal religious orders and the direction of the Spanish viceroys, who, like Vertiz at Buenos Aires and Juan Vicente de Guemes Pacheco de Padilla of Mexico, were sometimes enlightened and liberal men. Under these circumstances some of the old universities expanded their curricula to include all three forms of private law (Roman, canon and Spanish), and especially to add the law of nature and nations, which in reality consisted of public law and political and social philosophy. It was the same sort of intellectual and university movement that was being developed at the same time and somewhat earlier, on a larger scale, in English North America by Franklin, Washington, Jefferson and others. One of these universities, Charcas or Chuquisaca, in Alto Peru (Bolivia) developed (largely clandestinely and in spite of the Inquisition) so far in these new directions that it became the political training center for the future leaders of the revolution in the southern half of the continent. Some of the northern universities, particularly in Venezuela, were also

carrying on a similar work. Then as now new and liberal doctrines found a congenial atmosphere in which to multiply and spread in the universities, although the teachers did not themselves openly, or perhaps even tacitly, espouse them.

The social science publications of this period were not numerous and were naturally largely colored by theology. Antonio López de Pinedo of Peru was the first of that country to achieve an international reputation in law. He made a collection of the laws of the Indies and wrote *Bulario indico*, dealing with the spiritual and ecclesiastical government of America. Gaspar de Escalona y Aguëro of Alto Peru (Bolivia) wrote *Gazofilacio regio perúvico* (Madrid 1647), a treatise on finance and administration celebrated in its time, and *Oficio del virrey*. Bishop Gaspar de Villaroël (born about 1587) of Ecuador became very famous for his *Tratado del gobierno eclesiástico* (1656). Another Ecuadorian writer, less well received at home, was Francisco Javier Santa Cruz y Espejo (born 1750). His writings on political and theological questions, especially his *Nuevo Luciano de Quito* (1779) and *Cartas riobambenses* (1788), as well as his periodical *Primicias de la cultura de Quito*, caused his exile to Bogotá, where he helped start the revolution of 1809. Most of the writings of this time were, however, perfectly safe. Another radical, Toribio Rodríguez de Mendoza of Peru, sometime rector of San Carlos, introduced toward the end of the eighteenth century the theories of Newton, Descartes, Bacon and Gassendi, and created chairs in the law of nature and nations and adopted the civil doctrines of Helvétius. Other Peruvian partisans of the new spirit in the social and legal philosophy of this time were Mariano Vivero, who taught the law of nature and made Spanish law independent of Roman law, Diego de Cisneros, Simón Cerdán and Vicente Morales, who became president of the court of Cadiz.

At the northern end of the continent of South America, in New Granada (Colombia) and in Venezuela, the reform movement in the social studies and in politics toward the close of the eighteenth century was perhaps strongest. In the former country Antonio Nariño (1765-1823) made a study of the United States government and organized a liberal group to study the French radicals. He translated the *Rights of Man* in 1794 and edited *La bagatela*, an advanced political magazine. He was imprisoned and sent to Spain, but escaped. The

revolution having failed temporarily, he went to England in 1820, where he studied political theory, especially that of Destutt de Tracy. In 1821 he was back in Colombia and was made senator. Francisco Antonio Zea (1770-1822), also sent to Spain for circulating the *Rights of Man*, edited the *Correo del Orinoco* (1818-21), a medium for advanced political discussion, and was called the Franklin of his country. Camilo Torres (1766-1816), another reader of forbidden books, wrote on colonial government, was professor of civil law in the university and the leading jurist of the country. José Vargas (born 1786), a Venezuelan, translated the *Social Contract* in 1809. This book was thereupon widely distributed throughout Latin America, being republished in Buenos Aires and elsewhere. Miguel José Sans (born 1754) founded in 1790 the Colegio de Abogados (Law College) of Caracas and initiated the teaching of civil law in the country. Juan Germán Roscio (born 1769), of Caracas, was largely responsible for the Venezuelan manifesto, or declaration of independence. His *Triunfo de la libertad sobre el despotismo* (Philadelphia 1817) combatted the Spanish system. To these names should also be added that of Antonio José de Irisarri of Guatemala (1786-1868), who belongs in spirit to this period, although of a somewhat later date. He was a revolutionary political writer of some solidity, publishing *El semanario republicano de Chile* (1813) and *El duende de Santiago* (1818). He completed his education in London in 1820, where he published *El censor americano*. In the same class belongs Louis Fernando Vivero (died 1842), who promoted the revolution in Guayaquil and was the author of *Lecciones de política*.

II. THE NINETEENTH CENTURY. This period falls into two subdivisions, each occupying about half a century. These are the periods of revolution and reaction and of reconstruction. The revolution began at both ends of the continent—in Buenos Aires and in Venezuela—in 1810, under the leadership of Belgrano, Moreno and San Martín on the one hand, and of Bolívar and other men just mentioned on the other hand. These men had been educated in the new political philosophy and they seized upon the favorable circumstances of the conquest of Spain by Napoleon to strike for political independence. Although they were men equal in political theory and outlook to our own revolutionary leaders, such as Franklin, Washington,

Jefferson, Adams and Madison, whom they frequently emulated, they had a much more difficult task to perform. The masses of their followers were mestizos, without the barest rudiments of instruction, grossly superstitious and almost brutal in their interests and habits, taught to depend for absolute dictation and direction upon a hierarchical church and large landholders of an entirely different culture and social and political outlook. The Spanish system had created this division of classes to safeguard its dominance. The new republican order now had to make headway against this social dualism at home as well as against foreign domination. This is the explanation of that half a century and more of defeated ideals of the great patriotic statesmen and of anarchy and revolution so vividly described by Sarmiento (1811-88) in his *Facundo; o civilización i barbarie en las pampas argentinas* (Santiago de Chile 1845) and *Conflicto y armonías de las razas en América* (Buenos Aires 1883). The struggle for intelligent self-government and against landed autocracy and privilege still continues in those countries where large numbers of native races have not yet been educated, as in Mexico and Venezuela.

It is significant of the changing balance of power in Latin America during the eighteenth and nineteenth centuries that the revolution sanctioned by the new political philosophy developed most effectively in the Rio de la Plata area, centering in Buenos Aires, the last of the great coastal regions to come under the Spanish type of civilization. In Brazil the revolution came much more normally, at first under the leadership of one of the princes of the house of Braganza, with a peaceful transition to local rule later. After the death of Mariano Moreno, the Rousseauian political philosopher of the revolution, in 1811, and following a period of shifting and uncertainty, Rivadavia came to the helm in 1821. Rivadavia was so like Jefferson in his basic political philosophy, although much less of an advocate of decentralization, that it should be noted that he spent the years 1816-21 in Europe, and especially in France and England, where he came into intimate contact with the liberal thinkers of the time, including Bentham and the elder Mill. He brought back with him the theories of these men as well as those in which Destutt de Tracy, Jefferson's friend, had restated the philosophy of the French political revolution and enlightenment. One of the first things Rivadavia did in

Argentina was to establish the University of Buenos Aires (1821), in which he had James Mill's *Elements of Political Economy* and Bentham's theories of law and of government taught as the foundation principles by which he hoped to reconstruct the social philosophy of Spanish America. In less degree, and less consciously and less articulately in some cases, the same sort of movement for the reconstruction of the political theory basic to the revolution was going on in all Latin America. Although political economy was only secondary, Rivadavia had a lively appreciation of the fiscal needs of his country, and he had political economy taught in both its applied and theoretical aspects in the University of Buenos Aires as early as 1823. Under the leadership of Dean Gregorio Funes (1749-1830) something of this new outlook was creeping into the old conservative University of Córdoba, and like changes of viewpoint were being effected in the universities in Peru, Colombia, Venezuela and Mexico. It was at this time that the social sciences as such entered into the Latin American universities, at about the same time as, or a little later than, the establishment of chairs in these subjects in the colleges and universities of the United States.

But academic instruction in the social sciences could not save the revolution in Latin America. The uneducated, superstitious and unsocialized masses were too numerous in contrast to the few enlightened leaders. It was easy enough to control the masses, but it was just as easy, if not more so, for the self-seeking and relatively unenlightened leaders to control and direct them with motives of plunder as for the public spirited and educated leaders to direct them toward the support of civic ideals. Consequently, Rivadavia and San Martín went into exile before 1830, the better type of leaders in all countries were retired from power, frequently executed or exiled, and men like the bloody Rosas of Argentina, the conservative self-seeking Santa Anna of Mexico, or the autocratic Dr. Francia of Paraguay, came into power on the shoulders of the ignorant, turbulent masses. This period of reaction lasted until about the middle of the century—1852 in Argentina and 1857 in Mexico—or longer, according to the cultural development of the countries. In this period the universities were reduced to shadows and in Mexico actually abolished. The tyrants suppressed the teaching of the social sciences and historical and political

writings almost ceased to appear, except in the less turbulent states of the west coast, as will soon appear from citations of the writings of the time.

In Latin America there is a closer connection between government and the social sciences than in this country. Teaching the social sciences in the universities is incidental or secondary to the pursuit of governmental service or the legal profession. There are few if any full time professorships in the social sciences. The professor of the subject ordinarily has a single course or occasionally two or three courses in various social sciences, while his income is derived primarily from his law practise or from some governmental position. This arrangement comes down from colonial times when the clergy taught one or more courses largely incidentally, and it has been continued because there are not public funds available for the creation of large departments in the social sciences, outside of law. Even in law the different specialties are usually divided into single courses among several professional men. Throughout the nineteenth century the various social sciences, excepting law, were limited to one or two courses, and these were taught along with law in a faculty or school called variously juristic science or jurisprudence, law or law and the social sciences. The practise of law, which, as in North America, was not popular before the middle of the eighteenth century, became the leading profession at the time of the revolution and after. The other great profession, the clerical, then fell into relative disfavor and throughout most of the nineteenth century the profession of the priest was ordinarily shunned by the best minds, because the church had usually been on the side of Spain and the conservative and undemocratic leaders and tyrants in the period of struggle for self-government.

It is also important to note that the chief interest of the law profession throughout most of the nineteenth century was in public rather than in private law. This fact, so different from what we know to have been the case in the United States, was due to a number of circumstances. In the first place the harder struggle of the Latin Americans for self-government compelled greater interest in public law and the philosophy of law, just as in North America in the years immediately following our own revolution. At that time in our history and throughout most of the nineteenth century in

Latin America there was a very strong interest in the philosophy of law and government as well as in specific legal rules. The subject of natural law, as well as that of canon law, was taught almost until 1900 in Latin American secular universities. Another reason for their great concern with public law is the fact that their legal heritage is from the Roman law, while ours is from the common law of England. Their law has for centuries been reduced to codes and principles and thus their legal system is a quasi-governmental system closely allied to their political and ecclesiastical principles and institutions. Court procedure is more like governmental or administrative procedure and their codes are similar to their constitutions, while our municipal and constitutional law belong to two very different categories. Their constitutions are simply great political codes, but somewhat less systematic and logically authoritative than their civil codes, although both are applied in actual practise in essentially the same way, i.e., by deduction from general principles.

Consequently, the Latin Americans have not in the past made any marked distinction between their law and the social sciences. For both they ordinarily use the same generic term—primarily ethical in significance—*derecho*, or right, in contrast to the more formal term, *ley*, or formal rule of action. Thus they speak of *derecho público*, *derecho político*, *derecho económico*, *derecho civil*, *derecho criminal*, etc. to cover such meaning as public (including constitutional), political, economic, civil and criminal law or right and policy. Furthermore, as has been intimated, their law schools have not been mere professionalized vocational schools, but have been schools of social science designed for the purpose of training governmental officials quite as much as private practitioners. There the students have pursued the subjects of government (*derecho público* and *político*), political economy (economics in our business sense is more recent with them) and sociology (which grew largely out of the old *derecho natural*), together with their *derecho civil*, *derecho comercial* and *derecho criminal*. Their constitutions are therefore in their minds in large degree political treatises, ordinarily formulated by their most learned professors of political science or *derecho político* and *derecho público*. Likewise their international treaties and documents, such as the Drago doctrine, have been produced by professors of *derecho público*

internacional and *político*, who were also employees of the state, possibly ministers of foreign relations or secretaries of state. In all Latin American countries the various forms of their private law (never as completely private or individualistic as ours) are, like their constitutions or public law, codified and fall into such divisions as civil, criminal, commercial, rural, mining and procedural codes. This codification began soon after the revolutions and has continued to the present day. It has a greater definiteness and certainty than our private law, is largely in the category of public law and saves much time, energy and expense in avoiding intricate technical trials in the courts.

Following the reestablishment and strengthening of the constitutional regimes after the middle of the century, the universities revived and began to pay more attention to the social sciences. By the end of the century canon law had practically disappeared from the curricula of the more progressive secular universities, which included all the old universities named above and the new national universities established, especially after 1860. Classical economics began to give way to a new and liberal functional economics by 1900, but in few institutions was more than one course taught; this might run throughout the year, and be followed the next year by a course in applied economics, which usually dealt especially with money, banking and public finance. International law, sometimes a double course (public and private), was taught in most of the universities in the latter half of the century and sometimes earlier. The courses in natural law began to be transformed into the philosophy of law early in the eighties. By the nineties the philosophy of law had split into two general types of courses, which tended in the direction of institutional history and general jurisprudence on the one hand, and of sociology and anthropology on the other hand, corresponding closely in each case to courses under these names given in our own universities and colleges at that time or a little earlier.

Perhaps the first course specifically called sociology in Latin America was given about 1900 by Dr. Ernesto Quesada of the University of Buenos Aires, although courses in the philosophy of law containing sections entitled sociology had been taught in the University of Buenos Aires by Antonio Dellepiane in the middle nineties, and possibly earlier in other universities. Although the Latin Americans

have been somewhat slow to change the names or increase the number of their courses in the social sciences, the content has been much the same as in other countries. Even in history, which had been taught throughout the nineteenth century in Latin America in some form or other, few universities offered more than two or three courses at the end of the century; these consisted usually of ancient, modern and the national history. Sometimes the division was merely between national and European or general history. The history of institutions sometimes appeared as a separate course, but it was perhaps more often taught in connection with the philosophy of law and the several forms of law—civil, political, international, criminal, etc.

The nineteenth century in Latin America, particularly toward its close, was reminiscent. There was a serious stock taking, an attempt to explain historically the character of the civilizations which had developed. Only a few of the vast number of these histories can be mentioned to illustrate this increased activity in history writing which came with the establishment of relatively stable governments and the renaissance of the universities. In Mexico Lucas Alamán's (1797-1853) *Historia de Méjico desde 1808* (5 vols., Mexico 1843-52), and *Disertaciones sobre la historia de la República Mejicana* (3 vols., Mexico 1844-52) illustrate the more critical methods. Alamán also organized the general archives of Mexico and established the Museum of Antiquities and Natural History. He was a member of the Massachusetts Historical Society and the Philosophical Society of Philadelphia. Manuel Orozco y Berra's (1816-81) *Historia antigua y de la conquista de Méjico* (5 vols., Mexico 1880) is a review of early Mexican life and institutions. Orozco was one of several Mexican historians who were stimulated by Prescott's work on Aztec civilization. José M. Maroqui's *La ciudad de Méjico* (1900) is the work of an archaeologist reconstructing the history of the city, while Antonio García Cubas' *El libro de mis recuerdos* (Mexico 1905) tells the story of the American invasion and the Maximilian episode. Among many other Mexican historians of this period should also be mentioned Joaquín García Icazbalceta (1825-94), Francisco Pimentel and Agustín Rivera, who reviewed interestingly the history of colonial times. García Icazbalceta, besides translating Prescott's *History of the Conquest of Peru*, brought about the publication of many manu-

scripts of colonial historical writers. In 1858-66 his *Colección de documentos para la historia de México* appeared in two volumes; in 1866 his *Apuntes para un catálogo de escritores en lenguas indígenas de América*; in 1886 the famous *Bibliografía mexicana del siglo XVI*; and in 1886-91 the *Nueva colección de documentos para la historia de México*, in five volumes.

Peruvian historians especially have been active since the revolution. In the latter part of the century we find such productions as Manuel de Mendiburu's *Diccionario histórico y biográfico del Perú* (Lima 1874-86), a treasure house of early data in eight volumes, Pedro Paz Soldán's *Diccionario de peruanismos* (Lima 1882), Mariano Felipe Paz Soldán's (1821-86) able histories of the independence and its aftermath in Peru and of the War of the Pacific (*Historia del Perú independiente*, 2 vols., Lima 1868-70; *Narración histórica de la guerra de Chile contra el Perú y Bolivia*, Buenos Aires 1884), and Sebastián Lorente's *Historia del Perú* (6 vols., Lima 1860-76), and his valuable *Historia de la civilización del Perú*. Also Félix Cipriano Zegarra's literary history of Peru should not be omitted. In the documentary field Manuel A. Fuentes (born 1828) published *Memorias de los virreyes* (Lima 1859) in six volumes and *Historia sagrada*, while Ricardo Aranda edited *Tratados diplomáticos y actos internacionales y políticos del Perú* (14 vols., Lima 1890-1911). Other important documentary collections are E. Larabure y Unanue's *Monografías histórico-americanas* (Lima 1893) and Manuel de Odrizola's *Documentos históricos del Perú* (5 vols., Lima 1863-77).

In Chile Juan Ignacio Molina's (1737-1829) *Compendio de la historia geográfica, natural y civil del reino de Chile* (2 vols., Madrid 1788-95) is an example of the earlier historical writing before independence. Claudio Gay (1800-72) wrote a *Historia física y política de Chile* to 1830 (26 vols., Paris and Santiago 1844-54). Late nineteenth century historical writing in Chile is represented by the *Historia general de Chile* (Santiago 1884-1902) in sixteen volumes, coming down to 1833, and the *Un decenio de la historia de Chile*, in two volumes, covering the years 1841-51 (Santiago 1905-06), both by Diego Barros Arana (1830-1907); by the history of the organization of Peru, 1831-41, by Ramón Sotomayor Valdés (1830-1904); by the numerous histories of periods and movements in Chile by Benjamín Vicuña Mackenna (1831-86); and by similar writings of Miguel Luis Amunátegui

(1828-87) and the later historians, José Toribio Medina, Crecente Errázuriz (born 1839) and Gonzalo Bulnes (born 1851). Medina and Errázuriz wrote on colonial history, the latter producing *Los orígenes de la iglesia chilena* (Santiago 1873), as well as histories of the conquest and growth of Peru. In Bolivia Ramón Muñoz Cabrera (1819-69) wrote *La guerra de quince años en el Alto Perú*, and *Vida y escritos de Bernardo Monteagudo*. Jorge Mallo wrote on the administration of Sucre, Jenaro Sanpués on other important administrations; Modesto Omiste wrote *Crónicas potosinas* (4 vols., Potosi 1893-96) and other works; J. V. Ochoa and Eufonio Viscarra wrote on the War of the Pacific. The last named was also the author of a history of Cochabamba. Noteworthy Colombian historical works of the nineteenth century are Pedro María Ibañez' (born 1854) *Crónicas de Bogotá y del antiguo virreinato* (Bogotá 1891), José Manuel Groot's (1800-78) *Historia eclesiástica y civil de Nueva Granada* (3 vols., Bogotá 1869-70), a most valuable work on early social institutions, José Joaquín Borda's (1835-98) *Historia de la Compañía de Jesús en Nueva Granada* (Paris 1870), and José María Rivas Groot's *Páginas de la historia de Colombia* (1907) in two volumes, dealing largely with constitutional, fiscal and administrative matters. Cuba also was fertile in historical writing in the nineteenth century, producing among other works the *Ensayo histórico de la isla de Cuba* (New York 1842) by Jacobo de la Pezuela, the *Historia de la esclavitud* (3 vols., Paris 1875-77), and *La supresión del tráfico de esclavos en la isla de Cuba* by José Antonio Saco (1797-1879), the *Diccionario biográfico cubano* (New York 1878) by Francisco Calcagno, the *Primeros historiadores de Cuba* (1838) of José Antonio Echeverría (1815-85), *La abolición de la esclavitud* (Madrid 1869), *La cuestión colonial* (Madrid 1869), and *La pérdida de las Américas* (Madrid 1869) by Rafael María de Labra (born 1841), the histories of the cathedral of Cuba and of English interference in America by Pedro Agustín Morell, and finally the seven volume biography of the Cuban hero José Martí by González de Quesada (1900).

Historical writing in Argentina was also voluminous in the nineteenth century. The *Ensayo de la historia civil del Paraguay*, Buenos Aires y Tucumán, in two volumes (Buenos Aires 1816), by Dean Funes long remained the chief historical account of these provinces. The ten volume *Historia de la república argentina* (Bue-

nos Aires 1883-93) by V. F. López (1815-1903) brought the history of that country down to 1852. He was also the author of *Razas del Perú anteriores a la conquista*, written while in exile in Chile with Mitre, Alberdi and Sarmiento during the tyranny of Rosas. Manuel Bilbao's *Historia de Rosas* (Buenos Aires 1868), Bartolomé Mitre's *Belgrano* (4 vols., Buenos Aires 1858-59), and *San Martín* (4 vols., 2nd ed. Buenos Aires 1890), General José M. Paz' epic *Memorias póstumas* of his campaigns in the revolution, in the civil wars and against Rosas (Buenos Aires 1855), Antonio Zinny's (born 1821) *Historia de los gobernadores de las provincias argentinas* (5 vols., Buenos Aires 1879-83), Mariano Pelliza's (1837-1902) *Dorrego* (Buenos Aires 1878), *Dictadura de Rosas* (Buenos Aires 1894), *Historia argentina desde su origen hasta la organización nacional* (5 vols., Buenos Aires 1888-97), and *Organización nacional*, Vicente G. Quesada's (1830-1913) numerous histories of movements and periods and especially his *Vida intelectual en la América española* (Buenos Aires 1910), Julio Victorica's *Urquiza y Mitre* (Buenos Aires 1906), José Manuel Estrada's *La política liberal bajo la tiranía de Rosas* (Buenos Aires 1873) and his *Historia de la república argentina*, as well as the several important works of Adolfo Saldías (1850-1914) on national evolution in Argentina, will serve to indicate the type and quality of the later nineteenth century historical writing in Argentina. The Brazilian historians were almost as numerous; their works include the classic *Historia geral do Brasil* (vol. i, 1854) and the *Historia das lutas com os Hollandeses no Brasil* (Vienna 1871) by Varnhagen, viscount of Porto Seguro (1816-78), the *Plutarco brasileiro* (Rio de Janeiro 1847), published in English as *Illustrious Men of Brazil* (1858), and the *Historia da fundação do imperio brasileiro* (Rio de Janeiro 1864-68) by João Manoel Pereira da Silva (born 1819), the national history of Joaquim Manoel de Macedo (died 1882), *O Brasil* (1889) of José da Silva Paranhos, baron of Rio Branco, the history of Brazilian poetry and literature by Silvio Romero, and the *Dom João VI* (2 vols., Rio de Janeiro 1908) of the celebrated Manoel de Oliveira Lima. In Uruguay the works of Andrés Lamas (1817-91), in particular his *Artigas, compilación de documentos para la historia del Rio de la Plata* (1849), were notable.

It will be observed from the representative titles here cited that Latin American historical

writing in the nineteenth century centered almost wholly about nationalist themes. Furthermore—a fact that is not indicated so clearly by the titles—these histories are much more philosophic and explanatory, or sociological, than those of the United States or of Europe. The philosophy of history survived late into the nineteenth century, even into the twentieth, in Latin America and has had a strong influence on the historical writing of these countries. There has been an overwhelming impulse to explain as well as to recount. Nowhere else do mere dates and formal facts count for less and nowhere else is the meaning back of the facts of history so eagerly sought. No doubt this emphasis upon explanation has often led Latin American historians into unintentional bias and misinterpretation, but it is not clear that they are more subject to this failing than other historians. One can say with certainty that their histories are ordinarily most interesting reading and from them one can gather some organic notion of the various factors that have been active in their national development.

The Latin Americans have been especially attentive to the subject of geography, since it has been so constant and important a factor in the determination of their national destinies. In addition to the works of colonial times, a few of the chief nineteenth century products in this field may be noted. Manoel Ayres de Casal's *Corografia brasileira* (Rio de Janeiro 1817) attracted the favorable notice of Humboldt. Tranquilino Sandalio de Noda (1808-67) began a *Diccionario geográfico de Cuba* with José María de la Torre, and a fellow countryman of his, Esteban Pichardo y Tapia (1799-1879), composed a *Geografia de la isla de Cuba* (Havana 1854-55), which was generally highly regarded. Carlos de la Torre (born 1858) wrote *La geografia de Cuba*. Colombia produced at least two geographers of note in the nineteenth century, Simón de Lavalle, author of *Geografia universal* (1814), and Pedro Acevedo, who wrote *Noticia sobre la geografia política de Colombia* (Bogotá 1825). M. Díaz Memos also wrote several popular texts for schools. The Venezuelan, Feliciano Montenegro Colón, published a remarkable political, social and economic geography of Latin America, *Geografia general*, at Caracas (1833-37), in four large volumes. Mariano Felipe Paz Soldán's *Diccionario geográfico estadístico del Perú* (1877) has to do primarily with political geography. A distinguished Bolivian geographer was Ma-

nuel Vicente Ballivián, who produced several works on Bolivian geography between 1887 and 1894. To his name should also be added those of Daniel Campos and José Manuel Pando (1849-1917). Geography, it has been stated, is the most fertile field of Chilean science. Probably the greatest of these productions was the *Geografía política de Chile* (2 vols., Santiago 1888), of Aníbal Echeverría y Reyes. Important also is Francisco Solano Astaburuaga's *Diccionario geográfico de la república de Chile*. In Argentina Estanislao S. Zeballos promoted the organization of a geographical society and himself wrote a record of his explorations under the title *La conquista de quince mil leguas* (Buenos Aires 1878). Since then many geographical works have appeared, including the scholarly *Geografía general de América* by Juan G. Beltrán. In Uruguay, Orestes Araujo published about 1900 a *Diccionario geográfico del Uruguay* (2nd ed. Montevideo 1912), which was concerned largely with social and political geography.

Political economy was rather formal throughout the nineteenth century in Latin America. No general works or texts of distinction were produced, although there were a great many monographs of merit on finance, money, immigration and agriculture. The recurring financial difficulties of the republics stimulated teachers, government officials and publicists to constant attempts at the economic analysis of these practical problems. The relative poverty in general economic theory and in comprehensive special treatises on economic problems was due chiefly to the fact that the incidental character of this subject in the universities prevented any considerable degree of specialization in the field. Even the textbooks in economics were nearly always imported from Europe. After the long vogue of James Mill in the first half of the century, the French economist Courcelle Seneuil, an advocate of the Manchester school, had much influence in Latin America. He was a professor at the University of Chile from 1853 to 1863 and reorganized the Chilean banking system. He was followed at the university by Miguel Cruchaga (1842-87), who wrote *Elementos de economía política*, *Estudios sobre la organización económica y la hacienda pública de Chile* (2 vols., Santiago 1878-80), and *Tratado elemental de economía política* (2nd ed., Santiago 1870). This last was one of the most notable works of its day in economic theory in Latin America.

Zorobabel Rodríguez, a pupil of Courcelle Seneuil, also continued his point of view. Other Chilean economists were Cristóbal Valdés, Manuel Miguel and Marcial González, author of *Estudios económicos* (1887). In Bolivia Pedro Terrazas' translation of Bastiat's *Harmonies économiques* and Samuel Oropeza's *Economía política* and *Finanzas bolivianas* (Sucre 1887) are also important. In 1891 José María Linares, who edited various economic and financial journals, was made professor of political economy in the law faculty of the University of San Francisco Xavier. Two Colombians, Juan B. Abello (1833-87) and Aníbal Galindo (born 1834), produced treatises on economics, *Leciones de economía política*, and *Estudios económicos y fiscales* (1880) respectively. Rafael Nuñez (1825-94) wrote *La crisis económica* (1886). In Argentina in the nineteenth century there was no work of distinction on political economy after the publication of Juan B. Alberdi's (1810-84) *Sistema económico y rentístico de la confederación* (Valparaíso 1854), published soon after the reestablishment of constitutional government in the fifties. Most of this time the Argentines were content to use a translation of Joseph Garnier's *Eléments d'économie politique*. However, Amancio Alcorta (1805-62) and the historian V. F. López taught political economy very successfully for many years, and in 1890 the latter reorganized the badly shattered finances of the nation. Many good monographs on the fiscal situation also appeared between 1870 and 1900, some of them being prepared by López and Alcorta. In the eighties there was a revival of interest in economic subjects in Mexico. Then were published, all in the City of Mexico, Carlos Pacheco's *Informe sobre colonización y terrenos baldíos* (1885), J. C. Segura and M. D. Cordero's *Reseña sobre el cultivo de algunas plantas industriales* (1884), Santiago Ramirez' *Noticia histórica de la riqueza minera de México* (1884), and Ricardo de María Campos' *La crisis monetaria* (1886) and *Datos mercantiles* (1889). Francisco de Friás' *La cuestión del trabajo agrícola y de la población de la isla de Cuba* (1860) was largely responsible for the beginnings of scientific agriculture in that country. Tranquilino Sandalio de Noda (*Memoria sobre el cultivo del café*, 1828) and Desiderio Herrera y Cabrera (born 1792) were other agronomists and economists whose writings promoted the economic development of Cuba. The chief Cuban theoretical work in political economy was Tranquilino Sandalio de Noda's

Tratado de economía política con aplicación á la isla de Cuba.

Sociology, although it had no separate existence in the university curricula, was at least equally productive. There was not sufficient national motivation to produce original economists and the Latin Americans were content to imitate. But their social situation was their own and it was unique. As Sarmiento had said in 1845, they had on their hands a constant struggle between civilization and barbarism. This struggle existed everywhere in Latin America, but the Argentines were perhaps most keenly aware of it and they produced the largest amount of work in sociology. Sarmiento and Alberdi were early leaders in this field. Esteban Echeverría preceded both of them in his thinking and published his *Dogma socialista* and *Plan económico* in 1846. Alberdi contributed in addition to his *Estudios económicos*, which was very largely sociological, also *Luz del día*, *El crimen de la guerra*, *Ensayos sobre la sociedad*, and Sarmiento wrote also *Argirópolis* (Santiago de Chile 1850), *De la educación popular* (Santiago de Chile 1848), *Recuerdos de provincia* (Santiago de Chile 1850), and numerous other sociological works. José María Ramos Mejía took up the burden sociologically, following the lead of Maudsley, Bagehot, Tarde and Le Bon. He began with *Las neuroses de los hombres célebres en la historia argentina* (1876-78) and closed with *Rosas y su tiempo* (1907). In between came *La locura en la historia* (1895), *Los simuladores del talento* (1904) and *Las multitudes argentinas* (1899). Perhaps the most candid of the Argentine sociologists in an age of candor and self-criticism was Agustín Alvarez (1857-1914), whose work overlaps the following century but in technique belongs to the nineteenth. His *Sud América* (Buenos Aires 1894), *Manual de patología política* (Buenos Aires 1899), *Educación moral* (Buenos Aires 1901), *Adonde vamos?* (1904), *La transformación de las razas en América* (Barcelona 1906), *Historia de las instituciones libres* (Barcelona 1909) and *La creación del mundo moral* (Buenos Aires 1912) afford an excellent sociological picture of the nineteenth century in Latin America. Juan B. Justo (1865-1928) should also be mentioned. His leading sociological works were *El método científico* (1896) and *La teoría científico de la historia y la política argentina* (1898). Most of the sociological writing before 1900 was an attempt at the interpretation of Latin American history. It was a local sociology, although ob-

viously and professedly it had been inspired by the work of Taine, Spencer and the French social psychologists. In Chile a similar sociological interpretation of history was undertaken by Simón Rodríguez (1771-1854), one of the inspirers of Sarmiento and Bilbao, as well as the teacher of Bolívar, in *Las sociedades americanas* (1828), and José Victorino Lastarria (1817-88), especially in his *Lecciones de política positiva* (1875) and his *Investigaciones sobre la influencia social de la conquista y sistema colonial de los españoles en Chile* (Santiago 1844), in which, according to Huneeus, he anticipated Buckle. Francisco Bilbao (1823-65), who wrote voluminously on American culture, must also be mentioned among Chilean sociologists of the time. But Chile also produced a more philosophic type of sociology, particularly in the early part of the century, as is evidenced by the work of Andrés Bello (1781-1865); José Miguel Varas (1807-33), a follower of Destutt de Tracy, in *Lecciones de filosofía moral*; Ventura Marín (born 1816), author of *Elementos de ideología*; and the *Tratado sobre las luces y las virtudes sociales* of Simón Rodríguez. José Gil Fortoul (born 1862) of Venezuela published in 1896 *El hombre y la historia*, and Rafael Nuñez of Colombia wrote *Ensayos de crítica social* (1860-74). Nuñez, who was president of Colombia, in 1883 introduced and expounded the philosophy of Spencer as a remedy for the prevalent political dogmatism fostered by his predecessors. Other Colombian sociological works of this period were *La iglesia y el estado en Colombia* (London 1885) by Juan Pablo Restrepo (1839-96), and *La educación de la mujer* by Medardo Rivas (1825-1901). Very early in the century a Peruvian, José Hipólito Unanue (1758-1833), produced *Ensayos sobre la educación de la juventud* and other works on the social aspects of education. An interesting sample of Cuban sociological writing, which quite generally has been more practical and concrete than that of the rest of Latin America, was the *Observaciones sobre la suerte de los negros en Africa, considerados en su propia patria y trasladados á las Antillas españolas*, by Juan Bernardo O'Graban (born 1782). Eugenio María de Hostos (1839-1903), a native of Porto Rico, published *Moral social* (Madrid 1901). Francisco García Calderón regards de Hostos as the most important Latin American philosopher after Bello. De Hostos long resided in Chile and taught there.

Throughout the nineteenth century the Latin

Americans made no clear distinction between political science and law, treating the former variously as *derecho público*, *derecho político*, *derecho constitucional* and *derecho internacional*. Courses in these subjects were given in the universities after the middle of the century, and in international law occasionally before that time. The term *derecho político* did not become common before the eighties or the nineties, when it had practically the same meaning we were beginning to apply to the theory of practical politics, or actual government. The early political leaders and philosophers drew largely from Rousseau; later they generally adopted the leadership of Bentham. The writings of de Tocqueville, Victor Hugo, Saint-Simon and Comte also had great influence. The noted Chilean lawyer and publicist, Francisco Bilbao, had studied under Lamennais in Paris. Lermnier's *Cours d'histoire des législations comparées*, 1835-36 (Paris 1836) had great influence upon the young Alberdi and his contemporaries. Other Europeans who influenced the political and social philosophy of Latin America were Quinet, Michelet, Fourier, Proudhon, Ahrens, J. S. Mill, Adam Smith, Say, Bastiat, Laboulaye, Bryce and especially Duguit and Léon Bourgeois among the more recent writers. Writers in the United States, especially those dealing with its constitution, profoundly influenced the Latin Americans. The works of John C. Calhoun were translated and published in four octavo volumes at Caracas in 1879. The constitutional treatises of Story, Kent, Curtis, Cooley and others were familiar to them through translations and were much quoted by them. These writings strongly influenced their own constitutional development, and it is a commonplace that very frequently the judges of Latin American courts followed North American supreme court decisions on constitutional questions down to 1900 or later.

Only a brief mention can be afforded of the writings in political science of the nineteenth century, although they were very numerous. Andrés Bello, a Venezuelan naturalized in Chile, philosopher, philologist, historian, sociologist, political scientist and reorganizer of the university at Santiago, was the real founder of the nineteenth century social sciences in Chile. He had resided in England from 1810 to 1829, where he came under the influence of Bentham and James Mill, and had then gone to Chile where he founded the Colegio de Santiago, and had taught among other things Roman

law, political and social science and international law. He was active in the preparation of the codes of the country and wrote *Principios de derecho internacional* (1840). He also supported José Joaquín de Mora in introducing the legal philosophy of Bentham into Chile, as earlier it had been introduced into Argentina through the instrumentality of Rivadavia. Other noteworthy Chilean productions were the constitutional works of Mariano Egaña (1793-1846), the *Elementos de derecho público constitucional* (2nd ed., Santiago 1848) by J. V. Lastarria, the founder of the faculty of law and political science at the University of Chile, and *La constitución ante el congreso* (2 vols., Santiago 1879-80), and *Estudios sobre derecho constitucional comparado* (Santiago 1889) by Jorge Huneeus Zegers (1835-89). The latter introduced the inductive method into the teaching of his subject and enjoyed a great reputation in Chile and elsewhere. His method was adopted and perpetuated by Valentín Letelier, who developed a new school in administrative law. In Bolivia the *Nociones de derecho público político* (La Paz 1898) and the *Nociones de derecho internacional moderno* of Federico Díez de Medina (1839-1904), the *Dogmas del derecho internacional* (New York 1870) of Agustín Aspiazú (born 1817), the *Derecho administrativo* (Sucre 1889) and *Derecho público constitucional* (1898) of José S. Quinteros, the *Derecho público* of J. M. Gutiérrez, the *Problemas políticos de la América del sud* (1895) and the *Derecho natural* of Luis Arce were important.

Colombian and Venezuelan writers on political science also have been numerous. J. M. Samper's (1830-88) *Derecho público interno de Colombia* (2 vols., Bogotá 1886); Federico C. Aguilar's *Colombia en presencia de las repúblicas hispano-americanas* (Bogotá 1884); Justo Arosemena's (1817-85) *Estudios constitucionales sobre los gobiernos de la América latina* (2 vols., 2nd ed. Paris 1878, first edition published in Paris 1870 as *Las constituciones de la América latina*), and *Apuntamientos para la introducción á las ciencias morales y políticas*; Rafael Nuñez' *La reforma política en Colombia* (Bogotá 1885); and the *Elementos de ciencia administrativa* (Bogotá 1840), the *Lecciones de derecho constitucional* (Buenos Aires 1869), *Las repúblicas sudamericanas y el "Uti rossidetis" de 1810* and *La libertad civil y el gobierno propio* (1872) of Florentino González (1806-75) are representative of Colombia. The last named work was a translation of Francis Lieber's *Civil Liberty and Self*

Government, published in 1853. He also translated J. S. Mill's *Representative Government* in 1865, and some of the state constitutions of the United States in 1870. His works were used widely throughout Latin America. Luis Sanojo's *Derecho político* (Caracas 1877) and José Gil Fortoul's *Filosofía penal* (1891) and *Filosofía constitucional* (1890) are fairly typical of Venezuela. Pablo V. Goyena's *Diccionario de la legislación rural de la república oriental del Uruguay* (Montevideo 1887) and his voluminous compilation of *La legislación vigente* (2nd ed. 1888) and Federico D. Acosta y Lara's *Los partidos políticos* (1885), one of the first works on this subject, *Filosofía del derecho* (2 vols., Montevideo 1890-94), and *Lecciones de derecho constitucional* may be cited for nineteenth century Uruguay. The *derecho público* of Argentina was comparable in development to that of Chile. In international law Carlos Calvo (1824-1906) and V. G. Quesada (1830-1913), voluminous and important writers and compilers of documents, Amancio Alcorta y Palacios (1842-1902), Luis M. Drago (1859-1921), author of the Drago doctrine, and Estanislao S. Zeballos were the outstanding figures. In constitutional law Alberdi, Sarmiento, V. F. López, J. M. Estrada, Francisco Ramos Mejía (1848-1900), in the latter half of the century, and Mariano Moreno, Bernardo Monteagudo, Rivadavia, Dean Funes and Dorrego in the early or revolutionary period, were the leaders. J. B. Alberdi, perhaps the greatest of the Latin American social scientists, was the author of the *Bases y puntos de partida para la organización política de la república argentina* (Valparaíso 1852), which served as the groundwork of the national constitution of 1853. The *Diccionario de legislación peruana* (Lima 1860) by Francisco García Calderón (1834-1905) of Peru has long been regarded as basic to public law studies in that country. Much the same may be said of the *Diccionario de legislación* of Germán Leguía y Martínez. The *Colección de los tratados* of Ricardo Aranda has already been mentioned. An early political philosopher and writer on public law was José María Pando (1787-1840) who wrote, among other things, *Pensamientos y apuntes sobre la moral y la política* (1837) and *Elementos de derecho internacional* (1843). Manuel Atanasio Fuentes (born 1828) wrote a *Derecho constitucional universal*. The Latin Americans have been much preoccupied with international relations because of their numerous boundary disputes and their financial difficulties with

European governments, and more recently with the United States.

In the field of law there was little originality in Latin America in the nineteenth century, aside from the fact that the primary interest was in public law, for which the Latin Americans had unique materials and needs. Their greatest contribution, not wholly underived from Latin Europe, whose system of private law they took over almost entirely, was the sociological emphasis in law, which long antedated the somewhat similar recent movement in the United States. This sociological trend in law and legal theory was in part the logical consequence of the foundation principles of the Roman civil law, but especially of the Comtean or positivist spirit which reached Latin America, chiefly through Taine, Spencer and Buckle, and found a very ready response there. The newness of their culture and the relative directness of the response they found it necessary to make to their physical environment gave an excellent background for the reception of positivism. But particularly the reaction of the first two generations after independence against the church, which they found so largely in opposition to their republican principles, confirmed them in this new viewpoint. As Huneus says of Chile, "modern positivistic science has delivered the study of legislation and law over to the dominion of sociology." The same might be said of other Latin American countries toward the close of the nineteenth century, although the transformation was wrought primarily through the subject called philosophy of law, which for half a century has been taught everywhere in their universities as an introduction to the study of law and legislation. But the content of this course has been primarily sociological and anthropological rather than legal and technical, as it has been in English speaking countries.

The law schools devoted their energies primarily to the study of principles and to the analysis of codes rather than to the study of the intricacies of judge made law, which is so necessary in common law countries like ours. They had records of cases; and important cases, with the arguments and opinions, were often published by the lawyers concerned. But case law never achieved anything like the overwhelming importance it has had among us. They were interested in the law largely as a social science and directed their efforts to its simplification and standardization. All forms of

the law were codified. These codes, quite naturally, were at first based on the Spanish codes, but later came to embody the best principles of the codes of other European countries, and showed an increasing tendency toward revision to fit local conditions as the demands of their development made this necessary. These codes and their frequent revisions were universally prepared by the law professors rather than by private practitioners and politicians. The law schools, after the decline in importance of theology with the successful issue of the revolution, assumed the most active educational leadership in all the countries and, with the exception of the state, became the most influential secular institutions.

We may summarize this very brief analysis of nineteenth century social science in Latin America by saying that the most significant developments were in history, political science and sociology. It was in these subjects and in geography, in which their own experiences counted for most, that they showed the greatest originality. Their peculiar practical political and social problems, especially intense during the first half of the century, placed a premium upon philosophic and sociological analysis and synthesis and made necessary the creation of a political science—*derecho político* and *público*—which would fit their own needs. The response in the social sciences, considering the poverty of their universities and the lack of opportunity for specialization, was highly creditable and significant. In the fields of law and economics, except for the socialization of their law and their work in those phases of applied economics which touched their own particular national problems, they were much less original. This was undoubtedly because of their retarded economic development and the inherited similarity of their domestic institutions to those of Latin Europe, from which they derived their law:

III. RECENT TRENDS. Many new developments were taking place in the social sciences in Latin America by 1900. The reorganization of the universities on a more modern basis began in the sixties and seventies and was becoming effective in the eighties. By 1900 the national universities—the best universities in Latin America are supported by the national governments—had become cosmopolitan in character and were beginning to take their place among the universities of the world. In 1910

Mexico reestablished her national university, and now every South American republic has one or more national universities. Argentina has five. The universities are also broadening their scope. The faculties of law and the social sciences, sometimes called law and the political sciences, continue to teach the social sciences, as they did throughout the nineteenth century. The national universities of Buenos Aires and Havana and the Catholic universities at Bogotá and Santiago have established faculties of philosophy and letters, in which history and the social sciences, including geography and archaeology, receive more adequate attention. The universities of Buenos Aires, the Littoral (Argentina), Uruguay, San Marcos (Peru), Chile and the National School of Finance and Commerce of Salvador have faculties of commerce and business administration built around economic studies. Chile has a Social Service School, the only one so far in Latin America, where scientific training for relief work has not been especially emphasized. This school issues a standard review, *Servicio social*. Venezuela has two schools of political science at Trujillo and Valencia. Rural economics and sociology are now being taught in most of the agricultural faculties to be found in all of the countries, and agricultural cooperation is being strongly promoted. In a number of countries, particularly in Colombia and Bolivia, there are separate schools of law in addition to those connected with the different universities. Generally only doctors and licentiates of the national or public institutions are licensed to practise the professions and are qualified to hold certain types of governmental positions. There have been some overt political conflicts of authority between church and papal representatives and the national governments, such as the recent one in Mexico and the famous expulsion of the papal nuncio from Argentina by President Roca in 1884, which help to explain these regulations. In addition to university instruction in the social sciences, these subjects are beginning to be included in the normal and secondary schools. Civics first followed history (an old subject) here, and now sociology and economics are being included in some places, notably in the Colegio Pedro II of Rio de Janeiro and various Argentinian schools. Accordingly, less emphasis is being placed upon the old classical studies. Educational reform, particularly of the universities, is much discussed and many volumes are issued dealing with this subject.

In some countries secular control of education has gone farther than in the United States. This theme is ably discussed in *Las dogmas, la enseñanza y el estado* (Montevideo 1927) by Professors J. C. Grauert and Pedro Ceruti Crosa of Uruguay.

Two leading trends in law have been manifest since 1900. One of these is toward a greater emphasis upon case law and less philosophic discussion of principles. This is due largely to the German and North American influence, especially in corporation law. On the other hand the philosophy of law has shown some tendency to become less positivistic and sociological and more neo-Hegelian and neo-Kantian. This second tendency is due largely to the influence of Bergson, Del Vecchio and Stammler, reenforced by the disillusionment regarding the omnipotence of science for good resulting from the late war. Law is the most prolific field of Latin American social science literature. Men like Alfredo Colmo and Alfredo L. Palacios (*El nuevo derecho*, Buenos Aires 1920) of the University of Buenos Aires are beginning to systematize and rewrite the principles of the civil law from a critical and sociologically constructive standpoint. International law perhaps still commands the strongest public interest. There have been numerous writers in this field, of whom Drago and Quintana of Argentina and Oliveira Lima of Brazil have perhaps been most outstanding. In constitutional law the large four volume work *Estudios constitucionales* (La Paz 1920) of José Carrasco of Bolivia and the works of José Matienzo of Buenos Aires deserve special notice.

The close relation between sociology and law is perhaps as well illustrated in *derecho criminal* (criminal law) as elsewhere. The subject is commonly divided in the universities into two fields or courses, general and special, which correspond pretty closely to our criminal law and our criminology and penology, respectively. Two interests have been active in criminology since the seventies. One has its source in the Italian school of criminal pseudo-psychiatry, only recently outgrown. The other derives from the North American school of penology, reenforced by modern European schools. The report and recommendations of the Cincinnati meeting of the National Prison Association of 1870, destined to be so influential in this country, were translated, published and disseminated throughout Latin America by a Colombian diplomat who attended the sessions.

This document went far toward fixing penological practise. Enrico Ferri also has had great influence upon Latin American criminological theories, but more recently the German penal code has been much consulted, especially under the leadership of Juan P. Ramos, professor at Buenos Aires. Dr. Jorge E. Coll, of the same university, has been very influential in introducing modern methods of correctional treatment of juveniles, as has also Ernesto Nelson.

The work of Matienzo in *derecho político*, or actual government, resembles in many respects that of such northern scholars as Beard, Young, Holcombe and Merriam. The Cuban, Francisco Carrera Jústiz (born 1857), has done important work in municipal affairs, writing extensively on city government, utilities and administration. He also founded the *Revista municipal y de intereses económicas* in 1906. Another Cuban, Enrique Hernández Cartaya (born 1877), has specialized particularly on the primary and has published, among other works, *El régimen electoral de la república de Cuba*. Other Cubans working in the field of politics and international relations are Gustavo Gutiérrez y Sánchez, Fernando Sánchez de Fuentes and Salvador Salazar. Two Bolivians, Daniel S. Bustamante and Federico Díez de Medina, have done important work in international relations. In Uruguay Luis Alberto de Herrera (born 1873), in international law, Baltasar Brum (born 1883), in international politics, Justino Jiménez de Aréchaga (born 1882) and Juan Andrés Ramírez (born 1875), in constitutional government and law, are typical of the work now being done in all the more advanced Latin American countries, too vast to be mentioned in detail. All of these men are, of course, teachers of their subjects in their national universities.

In history, critical scientific investigation has increased steadily since 1900. The University of Buenos Aires has been perhaps the most prolific center of historical investigation, beginning with the too little appreciated work of Juan Agustín García, whose *Ciudad indiana* appeared in 1900. Some of his students, notably Roberto Levillier, Ricardo Levene and Emilio Ravignani, have made investigations of a very high grade. The first, besides producing an excellent work entitled *Los orígenes argentinos* (Paris 1912), has in recent years been editing the early national documents pertaining to Peru, Bolivia and Argentina. Levene has written a very modern history of Argentina and has

specialized in the economic history of the Rio de la Plata region. His *Historia económica del virreinato del Plata* (La Plata 1927-28) is the standard in this field. Ravignani is director of historical research in the University of Buenos Aires. It is an interesting indication of the close relation of history and sociology in Latin America that the latter two men at one time taught sociology. Levillier's *Nueva crónica de la conquista del Tucumán* (vol. i, Buenos Aires 1926) is as much sociological and archaeological as historical. The works of David Peña and Rodolfo Rivarola in Argentina, of Vicente Dávila and C. Parra-Pérez (*Miranda et la révolution française*, Paris 1925, and *Bolívar*, Paris 1928) of Venezuela, of Ramiro Guerra y Sánchez (*Historia de Cuba*, vol. i, Havana 1921), Francisco Carrera Jústiz (*Historia de las instituciones locales de Cuba*) and Jorge Le Roy Cassá (*La historia y la prensa médica de Cuba*, 1917) of Cuba, must be taken as representative of scores of other historians throughout Latin America of whom space forbids mention. Many of these countries, like Mexico in its *Archivo diplomático mexicano*, are publishing authoritative series of historical documents carefully edited and interpreted by well-trained scholars. Likewise historical investigation of an adequate character is now being financed by the government and undertaken by private initiative in the more progressive of these countries, especially in Argentina, Chile, Venezuela, Brazil, Peru and Mexico. Some of the leading writers of texts in history since 1900 are Carlos Navarro y Lamarca (Argentina), M. Ordóñez López and L. S. Crespo (Bolivia), João Ribeiro (Brazil), C. J. A. Villacorta (Central America), L. Galdames (Chile), J. M. Henáo and G. Arrubla (Colombia), Ramiro Guerra (Cuba), C. Desruge (Ecuador), Luis Pérez Verdía (Mexico), C. Báez (Paraguay), C. Wiese (Peru), Hermano Damascenas (Uruguay) and Felipe Tejera (Venezuela).

Archaeology has been cultivated largely in connection with history as well as independently, and much good work has been done. Florentino Ameghino's (1854-1910) *Filogenia* (Buenos Aires 1884) and *Antigüedad del hombre en el Plata* (2 vols., Paris 1880-81) have not withstood the test of time, although they are widely known. Aristides Mestre (born 1865) and José Varela Zequeira (born 1859), both Cubans, wrote works of an anthropological character, the former in his *El problema de la colonización* (1887) and the latter in his *Carácter*

actual de los estudios antropológicos (1889). Mexico, Chile, Bolivia, Peru and Argentina have been most active in developing these fields of social science. There have been several prominent men in Mexico in this field, including Crescencio Carillo y Ancona, an early writer, Marcos E. Becarra, F. Belmar, Leopoldo Batres and Alfonso Caso. Other typical workers in this field are Luis Montané of Cuba, José Arrechavaleta of Uruguay, Ernesto Restrepo Tirado of Colombia, José Toribio Medina and Tomás Thayer Ojeda of Chile, Moises Bertoni, Carlos Fiebrig and Tomás Osuna of Paraguay, Arthur Posnansky of Bolivia and Juan B. Ambrosetti of Argentina. Two Germans who have done distinguished service in standardizing archaeological work in Latin America are Max Uhle, formerly of Lima and now at Quito, and Hermann Beyer, now at Tulane University. There is also an International School of Archaeology and Ethnology in Mexico. Professorships in archaeology and in anthropology have been established in the leading universities.

It was around 1900 that Ernesto Quesada added to the prevailing nationalistic sociology a more systematic theoretical treatment of sociology (*La sociología*, Buenos Aires 1904), which won the applause of Lester F. Ward. This lead was followed in Argentina by Alfredo Colmo (*Principios sociológicos*, Buenos Aires 1905), Enrique Martínez Paz (*Elementos de sociología*, Córdoba 1911), J. A. García (*Apuntes de sociología*, Buenos Aires 1909, 1912), Raúl Orgaz (*Estudios de sociología*, Buenos Aires 1915) and José Oliva (*Sociología general*, vol. i, Santa Fé 1924) of the same country, and by Mariano H. Cornejo (born 1866), of Peru, who wrote *La sociología contemporánea* (revised and translated into French as *Sociologie générale*, 2 vols. Paris). The writers on general sociology in Latin America were influenced by Comte, Spencer, Tarde, Durkheim, and more recently by Prieto, Simmel and Spengler, and by North American writers through Spanish and French translations made by Adolfo Posada and others. L. F. Ward, Giddings and Ellwood have successively exercised much influence. Cornejo has been influenced mainly by the folk psychology of Wundt, Valentín Letelier by the positivism of Comte, Orgaz by Simmel. But general sociology as a basis for legal and legislative interpretation has suffered recently from competition with the neo-Kantian and neo-Hegelian spirit in the philosophy of law. Nationalistic sociology is still dominant in Latin America and will con-

tinue to be so for some time to come. Among the writers of this type since 1900 José Ingenieros (1877-1925) of Argentina, author of *Sociología argentina* (Valencia 1913), *Criminología* (Madrid 1913), *La evolución de las ideas argentinas* (vols. i and ii, Buenos Aires 1918-20), etc., was clearly preeminent. Other prominent sociological writers of this period are Daniel S. Bustamante (*Principios de sociología*), M. R. Paredes (*Política parlamentaria de Bolivia*), Alcides Arguedas (*Pueblo enfermo*, Barcelona 1909), Bautista Saavedra (*El Ayllu*, Paris 1903), of Bolivia; F. J. Oliveira Vianna (*Psycologia social*, 1921, and *Populações meridionaes do Brasil*, 1920), of Brazil; Fernando Ortiz y Fernández (*El hampa afro-cubana*, Madrid 1906, *La reconquista de América*, Paris 1910, and numerous works on Negro and immigrant criminality, nationality, race, culture, etc.), Francisco Carrera Jústiz (*Sociología municipal, Estudios de economía social, Estudio de sociología política, Conservadores y liberales, Estudios político-sociales*, Havana 1911, *El socialismo municipal*, etc.), Pablo Desvernine y Galdós (born 1854) (*El derecho y la sociología*), Orestes Ferrara (*Machivavel*, Paris 1928), Ramiro Guerra (*Azúcar y población en las Antillas*, Havana 1927), of Cuba; Antonio and Alfonso Caso, Toribio Esquivel Obregón, Ezequiel Cháves, Vicente Lombardo Toledano, Norberto Domínguez and José Vasconcelos, of Mexico; Justo P. Prieto and Ignacio A. Pane (*Apuntes de sociología*, Madrid), of Paraguay; Carlos Vaz Ferreira, José Enrique Rodó, Emilio Frugoni and Alberto zum Felde of Uruguay; and A. L. Palacios (*La fatiga y sus proyecciones sociales*, Buenos Aires 1922), José M. Paz Anchorena (*La prevención de la delincuencia*, 1918) and Juan B. Justo (*Teoría y práctica de la historia*, Buenos Aires 1909), of Argentina. Much in applied sociology, in the fields of criminology, immigration, standards of living, juvenile welfare, etc., is also being written, especially in Cuba, Chile, Uruguay, Argentina and Brazil, but cannot be mentioned in detail. These fields of interest, excepting criminology and immigration, date almost wholly from 1900 or later. One of the most influential of the nationalistic and philosophico-ethical sociologists of the early twentieth century is Francisco García Calderón, the younger (born 1883). His *La creación de un continente* (Paris 1912) is one of the better surveys of the evolution of Latin American institutions. *Les démocraties latines de l'Amérique* (Paris 1912, translated into English as

Latin America, London 1913) is perhaps the most telling of Latin American defenses of the Latin civilization against the Anglo-Saxon. *Le Pérou contemporain* (Paris 1907) is an analysis of Peruvian civilization, while his *Hombres é ideas de nuestro tiempo* (Madrid), *Profesores de idealismo* (Paris) and *Ideologías* (Paris) are studies and appreciations of leading European and American social thinkers and thought. *Los países de la América latina* (Madrid 1915) of Alfredo Colmo of Argentina is one of the more dependable sociological analyses of Latin American civilization in some of its more fundamental aspects.

The development of economics since 1900 has been most striking both in the universities, as previously mentioned, where various faculties or schools of commerce and business have been established since 1903, and in journalism. Still, however, the economics treatises deal almost wholly with practical economic problems, and especially with finance. No first rate general work on economics has yet been written or published in Latin America. This is perhaps due largely to the fact that practical problems are too pressing and the professors still lack sufficient time for an adequate presentation of theory. This preoccupation with the practical problems of society is generally characteristic of sociology, political science and even history, as well as of economics. For their general theory they are usually content to depend largely upon writers in other countries.

It would, however, be a mistake to suppose that there are not able economists in Latin America. A few examples of such are Guillermo Subercaseaux (*Monetary and Banking Policy of Chile*, Oxford 1922), Santiago Marín Vicuña (*Los ferrocarriles de Chile*, 4th ed. Santiago 1916), Julio Zegers and Marcial Martínez, of Chile; Gutiérrez Darío (*Política económica*, 1910), Manuel A. Elías (*Finanzas prácticas de Bolivia*, La Paz 1915), José Gutiérrez Guerra (*Cuestiones bancarias*, La Paz 1910, and *La reforma bancaria*, La Paz 1913), Casto Rojas (*Cuestiones económicas y financieras*, La Paz 1909, *La moneda de oro en Bolivia*, Lima 1912, *Historia financiera de Bolivia*, La Paz 1916, etc.), of Bolivia; Leopoldo Cancio y Luna of Cuba; Eduardo Acevedo (*Economía política y finanzas*, 1903, *Historia económica y financiera de la República Oriental del Uruguay*, 2 vols., Montevideo 1903, *Legislación obrera*, Montevideo 1914, and *Temas de legislación financiera*, Montevideo 1915), Pedro Cosío (*Accidentes del*

trabajo, 1908, *Tarifas de aduana*, Montevideo 1910), Gabriel Terra (*Economía política, La industria lechera and Unificación de deudas del año 1883*), of Uruguay; Enrique Martínez Sobral and Carlos Díaz Dufoo, of Mexico; Lucas Caballero, Julio Caro, Alfonso López, Esteban Jaramillo, Simón Araujo, F. de P. Pérez and Enrique A. Gaviria, of Colombia; Eusebio and Elío Ayala and Rodolfo Ritter, of Paraguay; and Alberto B. Martínez and Maurice Lewandowski (*The Argentine in the Twentieth Century*, English translation, London 1911), Juan A. Alsina (*La inmigración europea en la república argentina, La inmigración en el primer siglo de la independencia*, Buenos Aires, 1910, *Población, tierras y producción*, Buenos Aires 1903, and *El obrero en la república argentina*, Buenos Aires 1905), Emilio Coni (in agricultural economics), Alejandro Bunge, Isidoro Ruiz Moreno, Juan B. Justo (translator of Marx and national senator from Buenos Aires), etc., in Argentina. The subject of statistics, although recognized throughout the nineteenth century, developed slowly until after the establishment of the schools of commerce and business, and it has not yet been applied to any considerable extent to the other social sciences.

Auxiliaries to the social sciences, such as public libraries, museums, professional periodicals and learned societies, have not been particularly well developed, owing to lack of financial resources, relatively small reading populations and insufficient specialization. Nearly all of the countries now have one or more historical reviews and economic journals. The law reviews are even more numerous. Practically all of the large national universities publish high grade journals to take care of the productions of their professors, and some of them issue series of research studies besides. There are also good journals in political science, but sociology, because it is more of a leavening spirit than an independent discipline, usually finds space in the other social science journals and in the philosophic reviews. Writers on archaeology, anthropology and geography depend largely upon the university reviews and studies, although some geographic societies have their own bulletins. The life of these journals is frequently precarious, for reasons mentioned, but when one disappears another, as a rule, soon takes its place. The scholars are not wholly dependent upon professional journals for publication, for the better dailies, such as *La Nación* and *La Prensa* of Buenos Aires, and

the numerous general magazines of the better class, such as *Nosotros*, *Amauta*, *Mercurio Peruano*, *Revista do Brasil*, *Cuba contemporanea*, *Revista Chilena* and *Sagitario*, constantly carry high grade articles in all the social sciences. In no other part of the world, perhaps, does the general periodical press sustain such a heavy load of scholarly material. This capacity results in part from the great interest of Latin Americans in learning and also from the fact that universal literacy and commercial advertising have not yet combined to degrade the character of their publications. The retail business is still carried on in relatively small units. It should also be noted that most writers and teachers in the social sciences have or have had some connection with serious general journalism, either as contributors or as editors. Most of the leading general reviews are edited by university professors, and professors are very frequently employed on the staffs of the great dailies.

The public libraries have not until recently been adequate for research purposes. There are only twelve libraries in Latin America with 100,000 or more volumes each. These are the national libraries of Mexico, 800,000; Chile, 783,956; Buenos Aires, 425,000; Cuba, 207,423; Costa Rica, 100,617; Colombia, 100,000; Uruguay, 100,000; Library of the Brazilian Historical and Geographical Institute, 124,000; Portuguese Library, Rio de Janeiro, 100,000; Buenos Aires public municipal library, 100,900; the library of the University of La Plata (Argentina) 110,000; and the library of the Academy of Sciences, Havana, 101,000. Of these 3,052,000 volumes, approximately, in the twelve leading libraries of Latin America, 636,000 volumes, or more than one fifth, are in Argentina. This predominance in books is paralleled by her predominance in most other respects. It is to be noted that all of these twelve libraries combined have about as many volumes as the Harvard University library alone contains. Only one Latin American university library contains as many as 100,000 volumes. Other university libraries most nearly approaching this in size are those of the Catholic University of Chile, 50,000; University of Lima, 47,000; University of Córdoba (Argentina), 35,000; University of Havana, 30,000 volumes. The bar association of Buenos Aires has a library of 32,411 volumes and the faculty of economic sciences of the same city has 9030 volumes. The public library of the Sociedad

Económica de Amigos del País (Friends of the Country) of Havana contains 60,382 volumes. The largest public libraries are La Paz municipal, in Bolivia (30,000 volumes); Santo Domingo municipal, in the Dominican Republic (2014); Guayaquil municipal, in Ecuador (32,687); National, in Guatemala (24,000); National, in Honduras (15,000); Panama (10,500); National, in Paraguay (12,000); National, in Peru (62,000); National, in Salvador (14,500); and National, in Venezuela (60,000). Argentina, Peru, Mexico and Cuba are fairly well supplied with books accessible to the public. Not all of these of course are social science books. One of the best libraries specializing in social science in Latin America is that of the faculty of law and the social sciences of the University of Buenos Aires. In 1926 it contained 17,000 volumes. Many of these libraries are uncatalogued or very inadequately catalogued. The memory of the librarian is the chief aid to be sought in locating books in such cases.

Under the circumstances here mentioned it may seem remarkable that any considerable amount of research could be done in the social sciences in these countries. But a great deal of excellent research is carried on in those which are more advanced. Public libraries of any size are relatively recent and are still but little used, comparatively speaking. Deficiencies of this sort have been made up largely by the splendid private libraries of the leading scholars. Vicente and Ernesto Quesada (father and son) accumulated a library of some 75,000 volumes, which is now in Germany, and Oliveira Lima, of Brazil, a larger one, now at Washington. Felipe Paz Soldán (Peru), José Toribio Medina (Chile) and E. S. Zeballos (Argentina) also collected large private libraries. There are similar private libraries in these and other countries, many of which contain from ten to thirty thousand volumes. Some of these are now being sold to public libraries in Latin America and abroad. One of the results of the growth of public libraries is the democratization of research in the social sciences and the increase of proletarian literature in this field. It is to be noted that the production and publication of radical literature are much more flourishing in Latin America than in the United States. Publishing methods are still comparatively primitive and publication costs are relatively low. Cast plates are still the exception rather than the rule, but the volume of pub-

lication, especially in the social sciences, is surprisingly large. Books are ordinarily published in paper covers at the price of one dollar to a dollar and fifty cents, a fact which encourages a large circulation. Book stores, both new and second hand, in the larger Latin American cities are more numerous and usually larger than in this country. The greatest handicap to publication is the small size of most of the countries, providing an insufficient cultural base and consequent meager buying power for literature discussing the national questions which constitute their chief concern. But the possession of a common language and civilization does much to offset this difficulty. Latin Americans still publish many of their books in Spain and in France, because of better publication facilities there and because it is often easier to distribute them to other Latin American countries from these centers than from any of their own publishing centers. They are also great readers of Spanish and French books, less of Italian and German books, and very little of English and North American publications. After the revolutions in Latin America, French thinkers dominated Latin American thought for three quarters of a century. But North American thinkers also had much influence until near the end of the nineteenth century, and many of our books were translated into Spanish.

Historical societies exist in practically every country. In some countries there are several such societies, with considerable collections of documents, periodicals and books. This is particularly true in Mexico, Peru, Chile, Colombia, Bolivia, Argentina, Cuba and Uruguay. The National Archives at Buenos Aires, for example, occupy a large building, the former post office of the nation, and consist of a vast number of precious historical documents, which are being gradually worked over into monographs under government patronage and by private initiative. In other countries similar processes are being carried out in more than a score of centers. Latin America is now one of the richest fields for historical research and it is only beginning to be exploited adequately. Research facilities in the other social sciences are less developed. Archaeology comes next in point of development, then anthropology, economic history and conditions, political problems, and sociological and social welfare data, constituting about the order in which materials and data are being collected and

interpreted at the present time. The research technique itself has not always been perfected or employed by Latin American scholars. Users of their books and materials are sometimes disappointed in the lack of definiteness with regard to facts cited, the absence or uncertainty of dates and other guides necessary to an adequate picture, faulty and indefinite citations of sources, proof-reading, indexing and the like. But in such matters of scholarship technique there is a rapid improvement.

By way of general summary, it may be said that under the colonial rule and the dominance of the clergy social science was limited almost wholly to history, archaeology, law and such phases of political and social philosophy as could be covered in canonical law, natural law (*derecho natural*) and theology. With the coming of the national period in the nineteenth century, law and history shifted largely to a political and sociological interest. This was especially true after 1850. *Derecho público*, and later *derecho político*, or practical government, dominated law and sociological interpretation dominated historical writing and teaching. This in large measure still continues to be true, but as the democratic tradition weakens and as the commercial and financial preoccupation of the people becomes more marked, there is an increasing emphasis upon private, civil and international law, and upon economics to the disadvantage of *derecho político* and sociology. Never has there been wanting originality in the manner of handling characteristic Latin American problems in social science, but the fact

that this civilization was less well developed than those of Europe and North America has made the Latin Americans in large measure dependent upon their distant neighbors for much of the method and content of that part of their social sciences which is not of indigenous origin.

Japan

The teaching and dissemination of the social sciences in Japan began after the historic Restoration of 1868, which marks the rise of the Japanese people as a modern power under Emperor Meiji. This restoration ushered in an era of renaissance which destroyed feudalism and gave rise to liberalism. Japanese thought, which had long been confined to ancient lore and immemorial traditions, was suddenly flooded with new ideas from England, Germany, France and the United States. For her revolutionary transformation, social, economic and political, and her astonishing progress in material civilization, Japan has been immeasurably indebted to the social sciences of the West.

The courses of instruction introduced into Tokyo Imperial University in 1871 included law, economics, political science and statistics. Since these subjects were hitherto unknown in Japan, the government invited instructors from France, England and the United States, and sent students to Europe and America who afterward returned to teach at the home university. Today the departments of social science in Japanese universities offer courses in law, political science, statistics, sociology, social politics, education, ethics, philosophy and philology. And in connection with all these branches of knowledge there are learned societies with official organs of publication (see appended list).

In the early years of Meiji Japan was in great need of legal advisers and legally trained government officials. Emphasis was therefore laid on the study of law, and a number of private law schools and colleges were established which even today occupy a prominent position among institutions of higher learning. With the advent of modern industrialism following the Sino-Japanese War of 1894-95, the importance of economics was recognized, and numerous public and private colleges and graduate schools came into existence for the purpose of giving instruction in economics and commercial science. At present, among social science publications, those on economics and social problems outnumber all the rest.

In the study of political science discussion during the seventies and eighties of last century centered on liberty and the rights of the people. The utilitarianism of Jeremy Bentham and John Stuart Mill was introduced by Yukichi Fukuzawa and Keiu Nakamura; the *Social Contract* of Rousseau and the philosophy of Montesquieu, by Chomin Nakai; the ideas of Herbert Spencer and of the German schools, by Hiroyuki Kato. Early students of political science and law, like Nobushige Hozumi, Kencho Suematsu, Kenjiro Ume and Nariaki Tomii, went to England or America; but later Germany attracted more Japanese scholars, and German schools began to acquire greater prestige.

The laws of Japan were drawn after European models. C. F. Boissanade, a Frenchman, and H. Rösler, a German, made respectively the first drafts of her criminal and her commercial codes. The constitution, promulgated in 1889, was based partly on the philosophies of Lorenz von Stein, Gneist and Spencer. At present, besides instruction in Japanese law, the universities offer as a rule courses in English, German and French law.

With the development of capitalism since the beginning of the present century, the idea of democracy, as propounded in America, has made a popular appeal. The peace movement and international questions are receiving more and more attention, and the League of Nations Association has branches in most of the universities and colleges.

Sociology, like other branches of the social sciences, developed under western tutelage. Shoichi Toyama, who went to England in 1876, occupied the chair of sociology at Tokyo Imperial University until 1897. He lectured principally on Herbert Spencer, and was an exponent of social evolution. Nagao Ariga was also a noted Spencerian in Japan. Tongo Takebe, who succeeded Toyama, was a follower of Comte and his positivism. It was Takebe who presided over the Japanese Institute of Social Science from 1912 to 1922, and published the ten volumes of its annuals. About that time,

at Waseda University, Riyukichi Endo held the chair of sociology, and delivered lectures which showed the influence of Giddings, Tarde, Durkheim and Simmel. Mention should also be made of Shotaro Yoneda, who studied personally under Giddings and Tarde and has been teaching sociology for the past twenty years at Kyoto University. He introduced into Japan various western schools of sociology, especially those of Germany and France, which command the largest following today.

The political economy of England and America was introduced into Japan during the period from 1860 to 1870 by Yukichi Fukuzawa, the founder of Keio University. A little later, Tameyuki Amano, a professor at Waseda University, appeared as a protagonist of the orthodox school of economics of John Stuart Mill. Still later, Kenzo Wadagaki and Nobu Kanai of Tokyo Imperial University introduced the new German methods of A. Wagner and von Schmoller. Then, in opposition to capitalistic economics, appeared socialistic economics. Hajima Kawakami, a professor at Kyoto University until 1928, lectured on Marxism. It may be noted that today a considerable amount of empirical study of Japanese economic history is being carried on.

The modern industrialism which followed the Sino-Japanese War, and the marked capitalistic tendency that developed after the war with Russia inevitably and rapidly widened the gap between rich and poor, occasioning frequent conflicts between the two classes. The situation caused a group of socialists to organize an Association for the Study of Social Problems in 1897, and an Association for the Study of Socialism in 1898, while at Tokyo Imperial University scholars of the German school preached state socialism and the need of social politics. Finally the leaders of different branches of the social sciences organized the Society of Social Politics in imitation of the Verein für Sozialpolitik of Germany. The society opposed the doctrines of both socialism and laissez-faire, and while upholding the principle of private ownership endeavored to find a means of preventing class conflicts and of effecting social equilibrium through individual initiative and governmental authority. With this object in view the society published, up to the year 1919, articles by various writers in its *Proceedings of the Society of Social Politics* (12 vols.). In 1919 the Ohara Institute of Social Research was founded by private donation.

This is the largest institution of the kind in Japan; it issues the *Labor Year Book*, the *Year Book of Social Work* and other publications. Originally organized for the study of labor problems and social work, the institute of late seems more exclusively interested in Marxism.

In the field of social statistics Kyoji Sugi was a pioneer in Japan; he contributed greatly toward perfecting population statistics and the national census. Another scholar, Iwasaburo Takano, professor at Tokyo Imperial University until 1919, introduced the method of von Mayer; it is largely due to his work and teaching that the science has attained its present status. The names of A. Quetelet and Mayo-Smith may be mentioned among western scholars who have been influential in this connection.

Anthropology was introduced into Japan by an American, Edward S. Morse, who published an article in 1879 in the *Memoirs of the Science Department* (University of Tokyo, vol. i, pt. i) on his discovery of the shell mound of Omori, near Tokyo. Shogoro Tsuboi, who as a student assisted Morse in the excavation of the shell mound, was the first to occupy the chair of anthropology at the Imperial University, and it was he who founded the Anthropological Society of Tokyo in 1884. Léon de Rosny was the first man to make anatomical measurements of the Japanese as a racial stock, while E. Baelz made a detailed comparative study of the Japanese in relation with the Ainu, the Mongol, the Manchu, the Korean and other neighboring peoples. Anthropology during this period was largely based on Darwinian concepts, but later R. Martin's method of measurements was adopted, and also the sero-anthropological method. The study of physical anthropology is mainly connected with the department of science, and cultural anthropology with the department of letters. The most recent methods of approach are the psychological and the cultural-historical.

Adult education is being carried on by the central and local governments, as well as by private religious organizations and societies. They provide courses of lectures, utilizing evenings, holidays and vacation periods. These lectures correspond to the instruction given at continuation schools, and are also intended to give proper civic training. Occasional lectures and courses of lectures are given from time to time by various libraries and newspapers.

Heretofore the central government has done

practically nothing to promote labor education, although the Ministry of Education is now planning to conduct model workers' institutes once or twice a year. There are, however, a dozen or more labor schools in various cities conducted under the auspices of local governments, trade unions, the National Association of Manufacturing and Mining Labor Education, and the Tokyo Imperial University Settlement. The Cooperative Society of Labor and Capital is also engaged in labor education, and conducts at Tokyo an institution for that purpose called the School of Social Politics.

The principal societies concerned with the social sciences, and their publications, are as follows:

The Juridical Society, founded in 1884: *The Journal of the Juridical Society*, monthly.

The Association of Social and Political Science, 1869: *The Journal of the Association of Social and Political Science*, monthly.

The Kyoto Legal Society, 1906: *The Law Review*, monthly.

The Kyoto Economic Society, 1915: *The Economic Review*, monthly.

The Sociological Society of Japan, 1924: *The Japanese Journal of Sociology*, monthly.

The Anthropological Society of Tokyo, 1884: *The Journal of the Anthropological Society of Tokyo*, monthly.

The Statistical Society of Tokyo, 1878: *The Journal of Statistics*, monthly.

The Historical Society, 1890: *The Journal of History*, monthly.

The Kyoto Historical Society, 1916: *The Historical Review*, quarterly.

The Association of Municipal Research, 1922: *City Problems*, monthly.

The Teiyu Ethical Society, 1897: *The Journal of the Teiyu Ethical Society*, monthly.

The Ohara Institute of Social Research, 1919: *The Labor Year Book of Japan*, etc.

The Cooperative Society of Labor and Capital, 1919: *Social Reform*, monthly.

The Central Association of Social Work, 1908: *Social Work*, monthly.

The Faculty of Economics, Tokyo Imperial University: *The Journal of Economics*, quarterly.

The Faculty of Economics, University of Keio: *The Journal of Mita Society*, monthly.

The Department of Political Sciences, Waseda University: *The Waseda Political Science Review*. The Law Association, Waseda University: *The Law Review*.

The Kobe Commercial Institute: *The National Economic Review*, monthly.

The Tokyo Graduate School of Commerce: *The Study of Commerce*.

TEIZO TODA

XI

United States

The development of the social disciplines in the United States appears to fall into three fairly well defined periods: first, the formative period prior to 1860; second, the period of development and differentiation from 1865 to 1900 or later; and third, the period of maturation and synthesis, especially after 1900.

I. THE FORMATIVE PERIOD. Law and theology were the first of the social disciplines to secure constructive definition in the English North American colonies. Theology, although the most important college subject in this period—with possibly the exception of the classics—was only slightly and indirectly social in character, and may therefore be considered only incidentally in this article. Its primary aim was to provide formulae for the adjustment of man to the supernatural and only incidentally to secure a working adjustment of man to man. This latter function it early left to philosophy and, after the rise of the secular power in Europe, especially to law. Even in colonial Massachusetts, where theocracy held partial sway throughout the seventeenth and a portion of the eighteenth centuries, law was technically the basis of political control. By the end of the seventeenth century in Massachusetts the common law had definitely achieved the upper hand in political control, although it was well into the eighteenth century before the professional lawyer could claim any considerable respect and confidence from the people. The rule of the clergy during the first century or so was, however, aside from the strong personal influence they exerted, not so much through ecclesiastical law as through the common law. The clergy throughout the colonial period rivaled the lawyers themselves—still comparatively few in number—in their purchase and reading of law books.

At the time of the early English settlements Coke was expounding the common law in England, and at the period of the beginnings of a national spirit in the colonies, between 1750 and 1775, Blackstone brought forth his *Commentaries*. These were imported into this

country and were republished in 1771 at Philadelphia. In 1803 the first of five volumes of an edition of Blackstone with American notes, edited by St. George Tucker, professor of law and politics at William and Mary College, appeared at Philadelphia. After 1800, and perhaps even before, the new legal problems and relationships in the colonies began to cause a considerable divergence from the content of the English common law, with the result that American textbooks and commentaries began to appear. This divergence was perhaps strongest in the middle colonies and in New England, where the economic organization differed most from that in England. In 1790 James Wilson, a member of the Supreme Court of the United States, began a course of lectures on law in the University of Pennsylvania which apparently involved an American and local reaction to the English common law system. In 1794 Chancellor Kent of New York began his famous lectures on law, which were finally issued in 1826-1830 in his *Commentaries* in four volumes, long the outstanding general treatise on American municipal law and frequently used (especially the first volume) as a text in public law. Kent was followed and preceded by a long list of textbook writers dealing with special phases of the law, the more outstanding of whom were, in this early period, perhaps Story, Choate, Greenleaf and Wheaton. As the law became more complex and as cases accumulated, the commentaries of Blackstone and Kent no longer sufficed as literary sources and guides to the study of the law, and special treatises or textbooks, as they were called, appeared in increasing numbers. Before 1800 all of these textbooks—very few at the best—were English. The first American textbook was Caine's *Lex mercatoria americana* (1802). Joseph Story's first text, on *Pleadings*, appeared in 1805. The growth of the law was particularly active in the period between 1830 and 1867, and the textbooks produced included the best works of Story, Angell on *Corporations*, Walker's *Introduction to American Law*, Bouvier's *Law Dictionary*, Greenleaf's *Evidence*, Sedgwick's *Dam-*

ages, Parsons' *Contracts* and Browne on *Statute of Frauds*. All of these treatises were still, in revised form, in use in the 1880's. Law periodicals also began to be published after 1830, but none of those established before 1860 now survives, at least in its old form. Before 1790 only four incomplete series of law reports were prepared, and only one of these was published before 1800. After 1825, and especially after 1840, the number of reports and digests and other aids to the practising lawyer, as well as to the student, increased rapidly, until by 1860 there were already signs that the wealth of such publications was becoming a burden. The economic development of the country had proved a great stimulus to the legal profession, and the indefiniteness of the common law, dependent, as it was, primarily upon precedent rather than principle, had served to increase the volume of litigation in a rapidly changing economic and social order.

The lawyer himself began to be a man of great public importance after 1750, when life in the colonies was rapidly making a transition from local and individual problems to those having national and social significance. In such a situation the theologian and preacher were no longer competent to serve effectively as leaders, and as yet there was no group or profession of men trained in political theory and administration. Consequently the mantle of leadership now fell upon the professional lawyer, who at one time, especially in New England, had been mistrusted and despised. When the colonists succeeded to the government after 1775, the lawyers were almost the only persons with sufficient training to act for the people. Accordingly, with the new emphasis upon education and especially upon secular education, after about 1730 and particularly after 1750, instruction in the law also became popular. Burke was able to say in 1775 that "in no country perhaps in the world is the law so general a study." But such study was carried on in the offices of successful lawyers and by clerks and apprentices in the courts. Apparently the first formal instruction in law was established by King's College in New York in 1755, where the fourth year of the curriculum was described as containing, among other things, "the Chief Principles of Law and Government, together with History, Sacred and Profane." The College of Philadelphia announced in 1756 instruction in law in practically the same words. In 1773 King's College established a professor-

ship in natural law (which most probably included some instruction in municipal or civil law) with the Rev. John Vardill as professor. In 1779 William and Mary had a course on "Law and Police." Other colleges followed in the establishment of chairs in municipal law (frequently including government or public law), such as Pennsylvania (1790), Columbia (1794), Transylvania (1799), Middlebury (1806), Harvard (1817), Maryland (1823), Yale (1824) and Virginia (1826), with twenty-two additional colleges giving instruction in law before 1860. A number of private law schools, founded and taught usually by a single individual, also began to spring up, beginning with the Litchfield, Connecticut, school in 1782 or 1784. Altogether more than twenty of these were established in nine or more states before 1850. As the colleges and universities began to give more adequate attention to the professional training of lawyers after 1865, the relative importance of the private law schools declined, except possibly in large commercial centers where they still flourish primarily as short course night schools for students otherwise employed during the day.

But it was, after all, relatively a simple civilization in which the professional training of a lawyer could prepare adequately for political leadership. If legal training met the needs of the times better than theological training after 1750, a new sort of training in the social sciences became necessary for the guidance of the American people in their social development, especially after 1860. The beginnings of instruction in history and the social sciences are of course to be found much farther back. Ethics, politics, moral philosophy and history all appeared as separate subjects (although not as separate chairs or departments) in the Harvard curriculum for 1643, and American history was being offered at William and Mary as early as 1731. Languages themselves, to which so much emphasis was given until very recently, were not just a medium of instruction in grammar and syntax, as they finally came to be in their declining years, but embodied in the reading texts the best history and politics, and perhaps even economics, that had been written before the eighteenth century. Also, along with instruction in theology there was always teaching in the law of nature and of nations, which was more in the character of political philosophy and ethics than philosophy or metaphysics proper. The works of Aristotle, coming down from the

Middle Ages, and of Grotius, Pufendorf and, in the late eighteenth and early nineteenth centuries, of Vattel and Burlamequi, were in the curricula of the higher grade colleges. Especially after the first third of the eighteenth century, when secular philosophy began to have a place distinct and apart from theology in the curricula, was this social subject matter dealing with public affairs made available to young college students. In the College of Philadelphia in the 1750's all of these works, as well as the political and ethical writings of Locke, Hooker, Sidney, Harrington, Fortescue and Hutcheson, were listed in the course of study and, with individual variations, the same was true of the other colleges of the day and continued to be so until the social sciences proper entered their curricula about 1800.

Although the need for social sciences was felt before the middle of the eighteenth century they did not develop as separate disciplines with anything like the rapidity with which law developed. The reasons for this are clear. There was no outstanding profession to make these sciences their chief interest and occupation, as there was for law and theology. The governmental administrators who might have held this relation to social subjects were the "political" appointees of a "foreign" power which neither trusted the colonists nor was trusted by them, especially after 1750. Indeed it is only within the last half century that our governmental organizations have sought and established any considerable functional relationship with the social disciplines. Yet the Rev. Hugh Jones saw the need of such a connection in 1724 and proposed that William and Mary should be recognized as the training school for the civil service of the colony. Franklin also saw the importance of such a relationship and attempted to make provision for instruction in the social subjects in the College of Philadelphia, as is shown in his plan of 1749. In his plan these subjects were arranged principally under the generic curricular term "history." Other plans for national universities and research institutions, put forth by Washington in his will in 1789, by Benjamin Rush (1787), by "a private citizen of Pennsylvania" (1788), by Dupont de Nemours (1800) and by Joel Barlow (1806), emphasized without exception the necessity of giving instruction or of conducting research in politics, and most of them also emphasized the importance of political economy and history. This advocacy was further continued by Jeffer-

son and Madison and their contemporaries, and the tireless energies of Jefferson in behalf of training in politics and political economy finally made these ideals realities, first at William and Mary College, and then at the University of Virginia and various other colleges and universities.

Another early obstacle to the adequate development of the social studies on an inductive and factual basis, as distinguished from the logical and aprioristic basis used by theology and the law of nature and of nations which afterwards gave way to moral philosophy, was the lack of an adequate documentary basis. The municipal or common law had this basis in the decisions of the courts, which had been collected and reduced to some sort of order in the commentaries of Coke and Blackstone, and later in those of Kent and in the textbooks. But politics and political economy had no comparable documents. There were the works of Plato, Aristotle, Grotius, Hobbes, Locke, Montesquieu and other writers, but when these were departed from, the meager facts of recorded history afforded little from which to generalize except hearsay and speculation. As yet there was no methodology for the collection of contemporaneous facts and their generalization statistically or otherwise, such as we now constantly make use of in the social sciences. Historical facts, then the only considerable reliance for induction in the social disciplines, were still very meager and not always well tested and verified. The eighteenth century indeed produced some outstanding historians, such as Gibbon, Robertson and Hume, with a new sense of responsibility for the accuracy of their data and for the reliability of their conclusions, but even these were far behind the critical school of historians of the nineteenth century in these very matters. Yet history had more data for inductive generalization and for the construction of descriptive narratives than any other social discipline, and it was history that first developed an independent position in the college curricula and as a social discipline.

History in some form was taught and written from the beginnings of collegiate and cultural activities in the colonies. The earliest record of courses at Harvard (1643) lists history for the winter term. It was probably taught at William and Mary from its opening as part of the dichotomy of *historia naturalis* and *historia civilis*. In 1722 the Hollis professorship of divinity was established at Harvard, including

church history and Jewish antiquities. A history professorship was proposed for William and Mary by the Rev. Hugh Jones in 1724, and in 1731 the Rev. William Stith was teaching American history there. King's College listed "geography and history" in 1754, and the College at Philadelphia taught civil history by 1756. The College of New Jersey was teaching "geography and chronology" by 1761. At Yale ecclesiastical history was taught by President Stiles by 1778. The Rev. John Gross at Columbia taught a very comprehensive course in history, based largely on geography, from 1784 to 1795. It was not until well after 1800, however, that history generally disentangled itself from the classics and theology (the Bible) and achieved an independent footing. Even Jefferson, in his plan for the University of Virginia, was content to leave history tied up with the classical and modern languages, since even in his time most of the historical source material still remained embedded in these languages. There were neither adequate translations nor textbooks prepared for classroom use. Jefferson, in outlining a course of reading in modern history soon after the opening of the nineteenth century, was forced to draw almost entirely upon the contents of such voluminous standard works as those of Hume (of which he did not think very highly), Robertson, Gibbon, Rapin, Millot, Hallam, Voltaire and Russell. The Bohn translations, which made available for general use the best classical and modern works, did not begin to appear until well after the opening of the century. It was also about the beginning of the second quarter of the nineteenth century that a series of historical textbooks especially prepared for and adapted to college instruction began to take the place of the longer general narratives and the largely philosophical and partisan treatises of Bossuet, Montesquieu and Ferguson. Even these last named treatises had appeared, for the most part, late in the eighteenth century.

Historical instruction was also closely associated with a number of other subjects in the eighteenth and early nineteenth centuries. Among the most important of these were the subjects of classical and Jewish antiquities. It is difficult to discover just when these subjects arrived at the status of separate courses and had independent textbooks prepared for them, but it appears to be evident that from an early date the teachers of Greek, Latin and Hebrew felt the necessity of presenting explanatory material

regarding the geography, customs, institutions and history of the peoples whose language and literature they were teaching. They probably also realized the value of this means of giving a more formal instruction in those materials that we would now call the social sciences. Out of this movement doubtless came Fénelon's *Télémaque* and that very pretentious work on Greek civilization by J. J. Barthélemy entitled *Travels of Anacharsis*. The latter work appeared in France late in the eighteenth century, was well known in translation in America by 1804, and was intended to be used as a text on the institutions, laws, customs and history of the Greeks. Texts on classical and Jewish antiquities were very popular during the first half of the nineteenth century in the United States, Adam's *Roman Antiquities* (1791) and Nevin's *Summary of Biblical Antiquities* (1829-30) in particular having a wide circulation. For many students and general readers such works were practically the only sources of formal instruction in what we would now call politics, economics and sociology. History was also closely associated with geography throughout the colonial period, and indeed has not yet lost this connection. Franklin had emphasized this relationship in his plan of 1749, and the Rev. John Gross, professor of German and geography at Columbia College from 1784 to 1795, made it a living reality.

Ancient history was most emphasized in the eighteenth and early nineteenth centuries. Jefferson said as late as 1825 that only England and France among modern nations had histories worthy of study. Rome was still the great object of historical writing and teaching. Although before 1800 history was not much taught as a separate subject apart from the classics, theology and antiquities, it was appealed to by all of the leading statesmen and thinkers, such as John Adams, Hamilton, Madison and Jefferson, to justify their schemes and theories. Its prestige steadily increased as the spirit of inductive generalization, modeled after the growing work of the natural sciences, developed. Furthermore it represented the more democratic tendency in the college curriculum, while the classics stood for the aristocratic outlook, and theology was the embodiment of conservatism. History was at that time practically the only open door to an understanding of the thought and behavior of the modern world. In particular, American history was the only academic avenue to an understanding of

the American world in which the students and the general readers lived. Consequently practically all historical writing before 1825 had dealt with local American history, including an occasional excursion into United States history, after the national spirit had been formed by the republic. Among the more interesting of these were Winthrop's *History of New England from 1630 to 1649* (1790), Bradford's *History of the Plimoth Plantation* (ms. 1856), Prince's *Chronological History of New-England* (1736-55), Stith's *History of the First Discovery and Settlement of Virginia* (1747), Hutchinson's *History of the Colony of Massachusetts Bay* (1764-67), Belknap's *History of New-Hampshire* (1784-92), Chalmers' *Political Annals of the Present United Colonies* (1780), Hazard's *Historical Collections* (1792-94), Cotton Mather's *Magnalia Christi Americana; or The Ecclesiastical History of New-England* (1702), and Beverley's *History and Present State of Virginia* (1705). It is interesting to note that most of these histories dealt with New England, where consciousness of social destiny and of aim was strongest, but Virginia also was well represented.

After 1825 separate historical instruction was given with increasing frequency in the colleges, and modern history rather than ancient history was the first to gain independent status. Ancient history in most cases continued to be associated with the classics until 1860 or later. American history in particular began to be stressed in the colleges, perhaps as an expression of the growing national spirit. Although American history had been taught at William and Mary in 1731, there were apparently no imitators among the colleges before 1800. The first separate chair in history was established at Harvard in 1839, with Jared Sparks as professor. Sparks was interested mainly in modern history and particularly in American history, in which field he did most of his writing. He also edited Smyth's *Lectures on Modern History*, thus greatly facilitating the study of modern history in this country. Two other men who greatly influenced the development of history teaching at this early date were Thomas R. Dew, professor at William and Mary between 1826 and 1846, and president from 1836 until 1846, and Francis Lieber of South Carolina College and Columbia. Dew's *Digest of the Laws, Customs, Manners, and Institutions of the Ancient and Modern Nations* (1851) placed historical study on a singularly modern basis.

Teaching politics and political economy and philosophy as well as history, he was largely concerned with making the lessons of the past significant for modern students. This is a note in historical teaching that is apparent in much of the teaching of history in the second quarter of the nineteenth century and particularly in that of Lieber, Sparks and Bowen. Lieber, perhaps the greatest scholar in the social disciplines in the United States before 1865, was particularly interested in historical interpretation as a guide to social understanding. He became professor of history and political economy at South Carolina College in 1835, and transferred to Columbia College as professor of history and political science in 1857. Sparks' successors at Harvard, Bowen and Torrey, followed largely in his footsteps, with perhaps an increasing interest in modern European history; and other colleges, especially Yale, Michigan, Wisconsin, Virginia and Pennsylvania, instituted modern instruction in history, more or less completely divorced from the dominance of the classics and theology. In 1850 Pennsylvania established the first distinct chair in American history, under William B. Reed, and this chair continued its separate existence until 1856, when Reed retired.

After 1825 a new interest in the writing of history also developed. This interest was due in the main to two factors, rather distinct in their origins, but which fused and perhaps re-enforced each other in the end. One of these was the rapidly developing nationalistic spirit, already mentioned; the other was the increasing contact of young university men with European universities where they came under the influence not only of the new critical spirit in historical writing, especially manifest in Heeren, but also of the enthusiasm for historical study then arising, especially in Germany. Irving and Prescott wrote extensively in the field of Spanish and Spanish American history, and Motley in a closely related field, that of the Netherlands when they were asserting their independence of Spanish rule. Not yet, in the first half of the nineteenth century, was the romantic tradition of the Spanish civilization dead in this country. Even after 1865 we find traces of it in the writings of E. G. Bourne and a few others. Francis Parkman caught the spirit of colonial enterprise on the frontier and preserved to posterity in his remarkable series of histories this phase of our national civilization. But Bancroft, a student of Heeren, was the first to envisage in

its completeness the meaning of our national development and to reduce it to a historical picture. Whatever its errors of technique and of viewpoint and interpretation, Bancroft's history of the United States is a great monument to the new concept and understanding of our nationality, in this respect fully comparable to the more recent and more technically perfect works of McMaster, Rhodes and Channing. The histories of Tucker and Hildreth in this period are but weaker, and sometimes more sectional, negatives of the same general theme.

Interest in the social sciences was also strong in this period before 1860. In many respects, particularly in the colleges, it was keeping pace with interest in history. Already we have noted the strong interest of Franklin, Washington, Jefferson and Madison in instruction and investigation in practical politics. They realized that a self-governing people must also be highly self-conscious politically. But politics, in spite of this emphasis upon the subject by the early national leaders, found it very difficult to secure a separate foothold in the college curriculum. We have seen that ethics and politics were taught at Harvard in 1643, and the graduating theses of Harvard and other institutions in the early eighteenth century disclose a deep, if largely scholastic, interest in public questions. In 1754 King's College listed instruction in commerce and government. The College of Philadelphia had an introduction to laws and government in 1756. William and Mary introduced work in politics in 1779, and Yale sometime between 1777 and 1789. The widespread study of Grotius, Pufendorf, Hobbes, Locke, Burlamequi, Vattel and other political and natural law writers in this same century also testified to the interest of teachers and students in political philosophy.

The development of politics before 1860 occurred primarily in connection with moral philosophy, municipal or professional law, international law and history. Moral philosophy and international law were the successors of the old subject, the law of nature and nations, which began to break up into these two newer disciplines soon after 1750, when the impulse to realism coming from the new economic and political problems of the times was rendering the old metaphysical methods of the law of nature and nations school relatively obsolete. Political philosophy as such found a place in the new moral philosophy, while the data and rules of politics were best covered by inter-

national law, although this subject also for another hundred years carried a considerable, if decreasing, burden of speculation regarding the nature and sanctions of natural law. Local and national politics were as yet but poorly developed and could still be handled in connection with history, which was primarily political history, and municipal law. One of the phases of history, already mentioned in connection with Dew, Lieber, Sparks and Bowen, which began to obtain increasing recognition after 1825—the philosophic interpretation of history—had arisen in large measure as a means to the generalization of political, social and economic tendencies from the data of history. Consequently the philosophy of history was one of the avenues through which political philosophy was taught. The works of Montesquieu, Ferguson and Robertson, and even of Gibbon, well known in this country, emphasized this aspect. When Guizot's lectures on the *History of Civilization* appeared in the second quarter of the century, this work almost immediately became the vehicle for the political interpretation of European history. Hallam's *View of the State of Europe during the Middle Ages* also provided a similar, if somewhat less popular and less fascinating medium. Both of these books continued in frequent—Guizot's in almost universal—use until the eighties.

Politics also made another close contact with history through the development of constitutional history. Perhaps the earliest definite step in this direction was taken at Transylvania College. In 1813 an anonymously edited source book entitled *The Constitutions of the United States of America with the latest Amendments, also the Declaration of Independence, Articles of Confederation, with the Federal Constitution* was printed at Lexington, Kentucky, by Thomas T. Skillman. It was reprinted in 1825. Also Jefferson and Madison planned a course of readings in politics for the University of Virginia in 1825, including Sidney's *Discourses*, Locke's *Essay Concerning the true original Extent and End of Civil Government*, the *Declaration of Independence*, the *Federalist*, the *Virginia Report of 1799*, and the *Inaugural Speech* and the *Farewell Address* of George Washington. By 1854, when Bowen produced his *Documents of the Constitution of England and America*, even before the English work of Stubbs had appeared in the same field, the constitutional history approach to the study of American government had already become well established in our

colleges. The study of the constitution was in fact, aside from the study of international law, the chief content of courses in politics, until the nineties of the past century. On the one hand this formal approach through the constitution was historical, as already noted. On the other hand it was analytical and legalistic, or in the nature of public law. This approach was due to the influence of the instruction in law. The faculties of the early colleges were small, frequently limited to from three to five or six men. Also, the classics, mathematics, philosophy and theology were already firmly established. To add a new course was as a consequence a serious problem, if not actually prohibitive. As we have seen, the subject of law began to get a foothold in the more progressive institutions toward the end of the eighteenth century in response to popular demands and public needs. In a number of institutions, and particularly in those dominated by Jefferson—William and Mary, Transylvania and Virginia—and in Harvard and Columbia, professorships in law were established. Almost universally the professors of law also taught, as appendages, the social sciences. This was true at William and Mary as early as 1779, and St. George Tucker of William and Mary, who was the first to edit Blackstone for this country, carried on the teaching of politics as well as of Blackstone after his succession in 1789. Tucker himself wrote several treatises on politics, including *Of the Several Forms of Government*, *Of the Constitution of Virginia*, and *View of the Constitution of the United States*, aggregating 446 pages. He published these political writings as appendices to the first volume of Blackstone's *Commentaries* in 1803. When Kent's *Commentaries* appeared in 1826 the first volume immediately became a text in public law, especially in eastern colleges, where it was added to the *Federalist* in this capacity. The early lawyers had a strong political as well as legal interest, and it was not until near the middle of the century that instruction in law became so highly professionalized that its teachers and students lost contact with the governmental and public aspects of their subject. In the South, under Jefferson's influence, more attention was given to Rousseau's *Social Contract*, especially at William and Mary, and to Destutt de Tracy's interpretation of the political philosophy of Montesquieu, which was prepared at Jefferson's request. But, on the whole, the historical and public law aspects

of politics won out in spite of the manifest wishes of Franklin, Washington, Jefferson and Madison, due to the more strategic position and greater influence of history and law in the colleges. International law developed as a separate discipline, partly under the tutelage of the law schools and partly within the liberal arts colleges. The works of Wheaton, especially his *Elements of International Law* (1836) and *History of the Law of Nations in Europe and America* (1845), gave to the United States a high position academically in this field.

That the study of practical politics was not entirely dead after 1825, although largely overshadowed by political philosophy and constitutional history and analysis, is evidenced by the work of Lieber, who published his *Manual of Political Ethics* in 1838-39 and *On Civil Liberty and Self Government* in 1853. There were also other outstanding writings in the field of politics, although fewer than in history. John Adams had presented his theory of the true nature of government in his *Defence of the Constitutions of Government of the United States of America* in 1787-88. John Taylor, senator from Virginia and philosophical expounder of the Jeffersonian democracy, had written several volumes in the first quarter of the century developing his theme. Calhoun's *Disquisition on Government* (1851) and *Discourse on the Constitution and Government of the United States* (1851), although decidedly academic and Aristotelian for a practical politician, were nevertheless masterly works. Mansfield's *Political Grammar of the United States* (1834), Beverley Tucker's *Series of Lectures on the Science of Government* (1845), Grimke's *Considerations upon the Nature and Tendencies of Free Institutions* (1848) and Hildredth's *Theory of Politics* (1853) also deserve mention in this connection. The courses in moral philosophy which flourished throughout the first half of the nineteenth century and discussed political as well as social questions, often in a very realistic manner, also helped to keep alive a considerable interest in practical politics in the colleges. In a number of chairs or "schools" or departments of moral philosophy separate courses with such titles as the "Science of Government" and "Civil Polity" were offered, as was the case at Wisconsin after 1851 and at Mississippi after 1854.

Political economy more readily received separate recognition in the curriculum, partly because it was a more practical subject, but especially because there were textbooks that

could be used for instruction, at least from the time of Adam Smith's *Inquiry into the Nature and Causes of the Wealth of Nations* (1776). Also, political economy did not so readily lend itself to the methods of historical treatment, since the business man and the statesman wished to know present and future economic trends rather than the history of economic movements. As early as 1754 King's College included commerce in its curriculum, and in 1756 the College of Philadelphia listed the subject, "Introduction to Trade and Commerce." In 1792 a professorship in "economics" under the direction of Samuel Latham Mitchill was founded in Columbia College, but the "economics" was apparently agronomy. As early as 1784 professorships in commerce and agriculture were planned at Columbia, but there was evidently no other issue than that mentioned above. The beginnings of political economy proper are quite uncertain. Bishop Madison may have used the *Wealth of Nations* at William and Mary in connection with his general work in moral philosophy as early as 1784, but this is mainly conjectural. John Gross seems to have been teaching some political economy in his course on moral philosophy at Columbia in the late eighties, or at least in the nineties. In any case it is pretty clear that the *Wealth of Nations* was used as a text at William and Mary by 1800 or before, and that it continued so to be used, with perhaps some intermissions, until Destutt de Tracy's *Treatise on Political Economy*, translated and published at the instance of Jefferson in 1817, was introduced at that institution. William and Mary held a very prominent position in the early teaching of political economy as well as of politics in general, due to the influence of Jefferson, and this position was perhaps augmented in the administration of President Dew.

Probably the first chair bearing the title "Political Economy" was that of moral philosophy and political economy at Columbia College, occupied by Professor McVickar from 1818 to 1859. Harvard established a course, although not a professorship, in political economy sometime between 1817 and 1820. Torrey, the successor of Jared Sparks, became tutor in history and political economy in that institution in 1844. Bowen became McLean Professor of Ancient and Modern History and Instructor in Political Economy in 1850, and in 1871 Charles F. Dunbar occupied at Harvard the first chair devoted exclusively to political

economy in the United States. The second chair actually to include the title of political economy was that of chemistry and political economy organized at the College of South Carolina in 1824 and occupied by Thomas Cooper. Courses in political economy were established fairly rapidly in other colleges: at Princeton in 1819; at Dickinson in 1822, which organized a mixed chair in the subject in 1826; at Bowdoin in 1824, which had a lecturer in civil polity and political economy at that time; at Rutgers and Yale and Virginia in 1825; at Union in 1827; at Brown, Dartmouth and the College of Charleston in 1828; at Amherst in 1832; at Williams in 1836, where a chair in rhetoric and political economy was established; and at various other colleges thereafter. The subject was probably taught in every college of importance by 1860, although it achieved the status of a separate subject in the curriculum rather late in some of the colleges—as late as 1853, for example, at Pennsylvania. The first course in the economics of business, under the title of "Commerce, Political Economy and Statistics," was offered at the University of Louisiana (now Tulane) in 1849 by DeBow. But DeBow resigned in 1853 to become director of the census.

The literature of political economy, both of the academic and the non-academic type, in the period before the Civil War was much more voluminous than the literature of politics, especially if we eliminate political speeches and legislative addresses. Destutt de Tracy's *Treatise on Political Economy*, written by an immigrant, has been mentioned. McVickar's *Outlines of Political Economy*, adapted largely from McCulloch, appeared in 1825. That universal genius, Thomas Cooper of South Carolina College, published two closely related works on the subject: *Lectures on the Elements of Political Economy* (1826) and *Manual of Political Economy* (1833). Wayland's *Elements of Political Economy* (1837), Potter's *Political Economy* (1841), intended for his students at Union College, and Vethake's *Principles of Political Economy* (1838) were not very profound works, but were primarily the outcome of the attempts of the authors to teach a relatively new subject. Wayland at Brown and Vethake at Princeton, Dickinson and Pennsylvania successively did much to popularize the subject without themselves specializing in it to any considerable extent. The *Principles of Political Economy* of Henry C. Carey, published in 1837-40 at

Philadelphia, was a much more pretentious effort, although it did not wholly satisfy the teachers of his or of any generation. European texts were also largely used. Smith's *Wealth of Nations* was popular in Virginia and J. B. Say in the North. Bowen's *Principles of Political Economy* (1856), like Carey's later writings, defended the protective system.

This long formative period before 1860 may be characterized as one of emergence. History arose primarily out of theology, the classics and other foreign languages, where it had been a secondary interest, and it received separate integration as an academic subject by a process of separation from geography, antiquities, language and theology. As an academic subject it also had its origins in part in literary history, which had grown up from the chronicle and the narrative of adventures, arising from the almost universal desire to keep a record and to recall important events. Politics and political economy, on the other hand, sprang, academically speaking, in the main from the old law of nature and of nations and more immediately from moral philosophy. These subjects also had their foundations in the practical everyday interests and observations of people regarding their own world. In fact this practical contemporaneous basis of interest and stimulus became steadily stronger from 1750 to 1860 and served in an increasing degree to shape the content and method of the social disciplines. It transferred the emphasis from ancient to modern history, and especially to American history. It also made political economy largely a study of American questions, such as banking, currency, protection, credit and land systems, in spite of the strong European currents in theory in other directions. It could not, however, prevent politics from becoming largely formalized as the study of constitutional history and public law. The literary and controversial aspects of these two social disciplines, as distinguished from their purely academic aspects, were even more local and responsive to American issues and needs than their formal phases. And the same is true of literary history in the United States. Law, however, responded less markedly to the American environment, because it was based on the theory of precedent and had its origins in the English court decisions. But even law made a considerable response to local needs, especially after 1825, at first on its literary side and later on the side of juridical theory and practise. The most

characteristic aspect of the law in this period, after the acquisition of its academic status, was its increasing professionalization. History, politics and political economy, however, did not develop in the direction of professionalization, with the possible exception of politics at the College of South Carolina after 1835, but together contributed a very large addition to the general cultural values of the college curricula in this period. They were highly symptomatic of the expanding range of vision with regard to the richness and meaning of life in the modern world and particularly in America. At the same time they were making marked contributions to an attempt at a more specialized and effective adjustment of people to that world. All aspects of life—economic, political and social—were expanding rapidly in richness and complexity in the period between 1750 and 1860, and the growth and establishment of the social disciplines in the colleges and in the literature represent a sort of collective response to that fact. Although all of these disciplines were strongly influenced by foreign models and content, the growth of American individuality and of local response to local needs was after all marked.

II. THE PERIOD OF GROWTH AND DIFFERENTIATION. From the close of the Civil War to the close of the century, and even later, the social disciplines underwent important transformations and enjoyed a remarkable period of growth. It was essentially a period of differentiation of subject matter and of definition of scope and method. The increased attention given to the social studies has been almost astounding, especially from 1880 to the present time, and perhaps increasingly since 1900. Until after the Civil War the classics had ruled the curriculum of the colleges, and the general idea of culture spread abroad among the educated classes was that of a literary and esoteric type. Theology had ruled the colleges down to the middle of the eighteenth century, because the colleges were originally founded primarily to teach the doctrines of particular denominations and to train young men for the ministry of those doctrines. But with the establishment of separate chairs in divinity at Harvard (1722) and at Yale (1755) theology began to be segregated from the curriculum as a whole, and by the end of this century the curricula were pretty well secularized. In the larger colleges of the central and

southern states this had occurred by the middle of the eighteenth century. Now the teaching of theology began to be segregated into separate theological schools. But the theological spirit did not disappear from the American colleges, especially in the social disciplines, until nearly the close of the nineteenth century, when the development of the spirit and content of science had become so marked that mystical and aprioristic interpretations were no longer good form. Cliffe Leslie remarked in 1880 that the theological outlook in political economy was still dominant in the United States, and the same might have been said of the other social disciplines. Bancroft, for example, frequently recognized the hand of God in history.

This development in the direction of a definite group of social sciences was apparently due to a number of factors. One of the most important of these was the growth in volume of science, and especially of the social sciences, relative to the classical, theological and literary elements of the curriculum. The maturing of the industrial revolution had its effect upon the colleges in a number of ways. It made a heavy demand upon them for the training of industrial, commercial and financial experts to serve the corporations. As a consequence technical schools were established, beginning with engineering and mining, and progressing up through the more material and exact sciences to agriculture, business, education, journalism and social work. Law, medicine and theology had already undergone professionalization. As the industrial complexity reacted upon the social life to increase its intricacy, the guidance of the expert and the delegation of all sorts of functions to those trained to perform them became a patent necessity, extending even into those relations of life which had previously been regarded as essentially personal. At first the tendency was to establish special professional schools for the provision of such technical training, thus leaving the colleges to pursue their traditional classical and literary interests. But this trend was practically reversed by an act of the federal government which had no such end in view. In the sixties the Morrill Act was passed by Congress providing subventions to the several states that would establish colleges giving training in agriculture and mechanic arts. The poor and needy state universities, which had been fighting a drawn—in some cases a losing—battle with the denominational schools eagerly seized upon this subvention. Its ultimate effect was to

establish the practise of giving professional training in the colleges, which now rapidly expanded into universities. Even the private colleges now found it much easier to secure gifts from philanthropic persons, who had profited from the industrial and commercial development of the country, for technical training than for the expansion of the old classical curricula. The inevitable effect of all this was that the arts colleges, surrounded by the new spirit of scientific investigation and the emphasis upon the practical and the contemporaneous, found it necessary to expand their curricula if they wished to share in the growing prestige and prosperity of the universities. The universities had ceased to be cloisters and had suddenly become active, eager, functioning elements in the social order. The bold step of President Eliot in introducing and popularizing the elective system completed the conditions favorable to the growth of the social disciplines. The elective system gave them a chance to grow without establishing independent schools or colleges in the universities at a time when they were not ready for professionalization. The fact that the early development of the social disciplines, partially excepting law, occurred within the colleges of liberal arts undoubtedly had a most lasting effect upon these subjects. It prevented their premature professionalization and assured a marked theoretical and cultural development of their subject matter before this step was taken. It also gave them an opportunity to develop their content and subject matter when funds could not yet have been obtained for the establishment of separate divisions in the universities.

The new expansion first occurred in the subject of history. In 1857 the greatest teacher and writer in the social subjects in the United States, Francis Lieber, had been brought from South Carolina to Columbia, but his primary interest in history did not get full scope for its development, due to his preoccupation with political science and even with law in the latter institution. It was in 1857 also that Torrey succeeded Sparks at Harvard. By 1870 Torrey and Bowen, who taught political economy as well as moral philosophy, etc., had come to dominate the senior year at Harvard. After 1870 Torrey continued to develop in the direction of constitutional history and politics, and by 1884 there were no fewer than seventeen courses in these two subjects, and three more in Roman law, offered by eight teachers in this

institution. After 1883, when A. B. Hart and Edward Channing joined the department of history, the subject developed rapidly. Perhaps it was the brilliant leadership of Henry Adams, who taught at Harvard from 1870 to 1877, that gave the necessary impulse to expansion in the new history for which Torrey had laid the foundations. Since the nineties Harvard has been one of the leading centers for the training of instructors in history and politics or government in this country. What was happening at Harvard in the seventies and eighties was also occurring at Michigan, Cornell and Johns Hopkins, although in slightly different ways and with somewhat different emphases. In 1857 Andrew D. White had gone to a chair at Michigan, in which history was the leading subject taught. He had studied in France and Germany and had brought back with him a strong passion for the historical viewpoint and the scientific method of historical investigation. He introduced this new attitude at Michigan and imparted it to one of his students, Charles Kendall Adams, who also studied in Germany and later became White's successor when the latter left Michigan to enter politics in New York state in 1863, and later to become president of Cornell in 1867. Under these two men the work in history at Michigan was greatly expanded. In 1878 there were at least four instructors in the various phases of the subject. Until C. K. Adams went to Cornell the department at Michigan ranked among the four most important in the country in this field. What White and his successor had done at Michigan, White and an able group of men he gathered about him at Cornell did for that institution. At the opening in 1868 White organized a college of history and political science and associated with himself such men as Goldwin Smith, Theodore Dwight, W. C. Russel and W. D. Wilson (professor of moral and intellectual philosophy and teacher of the philosophy of history). In 1881 Moses Coit Tyler, C. K. Adams, Herbert Tuttle and Edward A. Freeman (as lecturer) were added to the staff of the college, which had by this time become somewhat depleted. The eighties marked the golden age of history at Cornell, for after that decade White's stimulating influence was removed.

The last example of the "big four" in history in the seventies and eighties was Johns Hopkins. This university had opened its doors in 1876, pledged to the German ideal of scholarship and

investigation, but it was not until 1880 that Herbert B. Adams became leader of the famous Hopkins seminar in history. He was almost as much political scientist and sociologist as historian, and Richard T. Ely was associated with him in the field of political economy. This seminar had perhaps the most brilliant group of students, destined later largely to dominate the academic situation in the social disciplines, to be found in the United States in the eighties. The work of a few other men in history should also be mentioned in this period of differentiation and growth. Frederick J. Turner, who received his early training under W. F. Allen, himself an able immigrant from the classics into the social studies, and his graduate training at Johns Hopkins, was added to the Wisconsin staff in 1889. His work in the history of the West amounts to the creation of a new field and a new method which has profoundly affected historiography in this country. E. G. Bourne's work in southwestern history at Yale and the work of McMaster and Thorpe at Pennsylvania indicated new paths of interest in these decades of expansion and differentiation. The literary work of Van Holst, although nominally in constitutional history, should not be neglected, since its departure in the use of informal documents of all types and its emphasis upon the life and action of the people had most important consequences, particularly upon McMaster and Woodrow Wilson. Burgess at Columbia, although primarily interested in political science, had considerable effect upon the development of the study and writing of American constitutional history and the history of reconstruction.

These were the men and the institutions that in the main shaped the development of historical study and teaching before 1890. They were inspired mainly from Germany, although the influence of Hallam, Freeman, Maine, Buckle and Greene in England and of Guizot in France was by no means inconspicuous. In fact no other historians exerted so profound an influence upon the teaching of history in the United States in the nineteenth century as Guizot and Freeman. But the broad, seductive generalizations of Guizot had already lost most of their charm for the more critical historians in the seventies. The famous dictum of Freeman that history is past politics and politics present history then began to take the field and held it until well into the nineties. History meant something much more inclusive to the first

generation of history teachers after the Civil War than it did to the succeeding generation. For them the world of ideas and of political action was in process of profound change, and they were not yet so detached by scholarly isolation that they were not profoundly and personally interested in this change and in its outcome. For the method of Guizot the scholarly German method was substituted, but the themes remained pretty much the same. The serious direct influence of Guizot may be said to have ceased with the publication of White's *History of the Warfare of Science with Theology in Christendom* in 1896. The interest in free political institutions, however, was dominant throughout this period before 1890. The favorite courses in history were constitutional history, and under the influence of the English constitutional historians it was the custom to trace the origins of American constitutional history back to English institutions. The disproportionate emphasis upon constitutional history did not diminish until politics began to differentiate from history in the nineties and particularly after 1900. In the seventies and eighties, under the influence of Freeman and Maine and the German institutional historians, institutional history other than constitutional began to be developed. Henry Adams at Harvard and Herbert B. Adams at Johns Hopkins perhaps best represent this trend. Henry Adams' seminar, consisting of Edward Young, Henry Cabot Lodge and J. Laurence Laughlin, produced as the result of their labors in this field an important piece of work to which they gave the title *Essays in Anglo-Saxon Law* (1876). All of the members of this seminar later became teachers at Harvard. H. B. Adams at Hopkins directed his students largely to the study of education in the South and of local institutions, with the result that a series of monographs of great value was produced. Burgess accomplished a similar work for the period of reconstruction.

The German influence was exerted primarily in the field of method, and it is here that the greatest transformation took place. History became critical in a degree not before achieved in this country, and more and more of the historians' attention was given, especially after the eighties, to the sources and dependability of their data and less to the meaning or interpretation of the facts. In this way history became much more accurate, but also perhaps less satisfying to those who wished to find in it an

explanation and a guide. This increasing technicalism in history was compensated for by some writers and teachers by a greater emphasis upon the value of literary style. This growing interest in method early manifested itself in the organization of historical seminars. The first of these was established in 1869 by C. K. Adams at Michigan and the second by Henry Adams at Harvard in 1871. The most celebrated was that of H. B. Adams at Johns Hopkins. The seminar soon became the accepted method of teaching graduate students, who worked on individual problems in their fields and brought their results to the seminar, where methods and problems of procedure were also discussed. The leader of the seminar might himself work on a special problem or occupy his time with lectures on methodology and sources. Some leaders did both. C. K. Adams' *Manual of Historical Literature* (1882) was obviously the outgrowth of his seminar lectures. Most of the leading teachers and directors of research in history gave some attention to the subject of methodology and bibliography. The finished products of the seminar were in the form of monographs and served usually as PH.D. theses. Preferably they were integrated about some central theme, as was the case at Harvard, Johns Hopkins and Columbia in the instances mentioned. The field of history itself began early in this period to be differentiated into a number of subdisciplines or ramifications. In almost every institution of considerable size there early arose divisions between American, European and ancient history. To these were added in various institutions such categories as ecclesiastical, constitutional, institutional, economic, modern, intellectual, oriental and social history. Although separate administrative divisions were not usually made for these, sometimes distinct chairs were given some such title as here mentioned. European history especially grew in importance in this period, due largely to increased contacts of American scholars with Europe.

In the field of politics there was not much obvious development or growth in this second period. The subject had as yet scarcely emerged as a separate discipline. Where courses were given they were primarily devoted to constitutional history and constitutional analysis. It was politics as Freeman used the term. At Yale President Woolsey was, however, treating the subject with more academic respect and was offering courses in political theory and, in 1849, international law from the political science

standpoint. In 1860 he published his *Introduction to the Study of International Law* and in 1878 his *Political Science*. He also edited the second edition of the *Political Ethics* and the *Civil Liberty and Self Government* of Francis Lieber in 1874. But the only outstanding collegiate development of political science in this whole period, as distinguished from history to which it was everywhere else subordinated, was at Columbia. Burgess went to Columbia from Amherst, where he had already discovered Mayo-Smith and Munroe Smith whom, in 1876, he had sent from there to Germany for advanced study. But it was not until 1880 that he organized his School of Political Science and gathered into his faculty as his associates Munroe Smith in history and Roman law and Mayo-Smith in social science and political economy, with C. R. Bateman in administrative law and Archibald Alexander in political philosophy. Before 1890 F. J. Goodnow had been added in administrative law, E. R. A. Seligman in political economy, W. A. Dunning in political theory, and H. L. Osgood in history. This was a remarkably strong department, and the work in this field stood out far above that in any other institution in the country at that time. The school bent heavily in the direction of history, as was the custom of the time, each teaching member through the eighties giving at least one course with a historical emphasis. It also included such work, then slight, as was given at Columbia in political economy and social science. The School of Political Science at Columbia became the fostering spirit and largely set the mode for later more extensive developments in history, economics, sociology and anthropology in that institution and many others. Other universities began to give more specific attention to political science soon after 1890. In the early nineties A. B. Hart was giving a course at Harvard on American government in practise, a departure which later led to his work on *Actual Government*, first published in 1903. W. W. Willoughby was added in political science at Johns Hopkins in 1897. The University of Chicago gave some attention to the present aspects of government from the time of its opening in 1892, but development in this subject was slow until after 1900. Goldwin Smith continued his work at Cornell through the nineties, but his interest was primarily in the historical aspects of his subject. Other universities were picking up the thread of a growing interest in actual government and present po-

litical problems, but in 1900 public law and constitutional history were still the dominant emphases in political science in practically every institution of the country and the number of separate departments of political science was exceedingly small. For the most part the subject was still under the wing of history.

Political economy was never as thoroughly under the influence of history as politics, although the titles presented above show that the historical approach was not an infrequent one. The German-trained leaders in this period, especially H. C. Adams, R. T. Ely, Edwin R. A. Seligman, Henry W. Farnam and Simon N. Patten, had a strong historical bias which was shown in their writing and teaching, but perhaps none of these men could be said to be exclusively or even primarily committed to this method. The best efforts of all of them, including even Patten whose major interest was in the theory of welfare, went into the solution of practical economic and social problems. The others did distinguished work on government commissions and influenced important phases of social and economic legislation. Before these men, and other prominent teachers and writers such as Laughlin, Taussig, Seager and Veblen, came to dominate the development of political economy, the contemporary and practical side of economics had been stressed effectively by such men as David A. Wells, Horace White, Edward Atkinson, W. M. Grosvenor, and Francis A. Walker, who were active from 1865 until 1890 or 1900. Walker was statistician, theorist and practical economist. His *The Wages Question* (1876) and *Money* (1878), White's *Money and Banking* (1895), and Wells' *Recent Economic Changes* (1889) were the ripe product of much keen observation in the field of applied economics and exerted great influence. Walker's *Political Economy* (1883) was the legitimate successor of Bowen's and Carey's works and the able competitor of Mill and Marshall. It, more than any other American work, served to bridge the transition from the old classical aprioristic economics to the newer and more inductive factual treatises of Ely, Fetter, Seligman, Seager, Johnson, Taussig and other contemporaneous writers that came to appropriate the field of university instruction about the beginning of the present century. By the time these newer texts were before the public the historical interests of the authors were capable of being compressed into a few introductory chapters, and the statistical approach was in

most cases as strongly emphasized, if not more so, than the historical. By 1890 the historical treatment had been standardized and segregated into economic history, under various titles, such as financial, commercial, tariff and economic history. One of the earlier outstanding writers in this field, especially as it related to finance and industry, was A. S. Bolles of the University of Pennsylvania, author of *Financial History of the United States* in three volumes (1879-86) and *Industrial History of the United States* (1878). Harvard University also early developed this middle ground between history and economics, at first under the leadership of Taussig and later of William Ashley, who became professor of economic history at Harvard in 1892. More recently Harvard has again taken the lead in this general field by emphasizing in the Graduate School of Business Administration the field of business history and by launching the *Journal of Economic and Business History*. At Yale Callender was also a pioneer in the subject of American economic history.

In 1876, according to Laughlin's study, made in 1892, of the teaching of political economy, there were thirty-eight colleges and universities teaching political economy, of which only three colleges offered as many as two courses in the subject, and these in each case consisted of an elementary and an advanced course. In 1892 Michigan was offering twenty courses, Chicago seventeen, Pennsylvania sixteen, Columbia thirteen, Harvard eleven, Wisconsin and Massachusetts Institute of Technology each nine, and Yale, Oberlin and University of Iowa six each. The growth was even more rapid in the following decades. The expansion in subject matter, students and teachers was equally marked. By the end of the century the subdivisions of theory, economic history, money and banking, public finance and taxation, labor, industrial and business organization, and transportation were well developed and various other subdivisions largely of a business character, such as agricultural economics, insurance, credit, factory organization and management, and advertising were in process of being launched. Statistics was a subject much broader, of course, than economics. It is a method applicable to the inductive study of all fields of science, but particularly of the social sciences. We find occasional evidences throughout the century that its possibilities were appealing to the best minds. We have already referred to the work of DeBow. The American Statistical Asso-

ciation was founded in 1839. It fell, however, to the lot of political economy, as the social subject dealing most actively with current phenomena which must be generalized for guidance in practical affairs and policy, to do most in the actual application of this method. The work of Walker was outstanding in this connection, and that of Carroll D. Wright, who divided his attention between economic history and applied sociology and put the Massachusetts and the federal bureaus of labor statistics on a scientific basis, was perhaps even more influential. Wright and Walker made the statistical method a reality in governmental investigation, and they and Mayo-Smith dignified the subject with respectable college standing.

This period of growth and differentiation also gave rise to a number of new social sciences, theoretical and applied. Among these anthropology and sociology were the most striking examples. Although the origins of these two disciplines were not identical, their fields for a long time were closely related and only recently have they come to be fairly well differentiated administratively. Both grew out of a desire to apprehend the meaning of human behavior as a whole and to integrate human relationships rather than to atomize them. As anthropology—earlier called ethnology, because it was commonly believed in the nineteenth century that there could be a science of race on the social side—developed, it was concerned primarily with the data of primitive peoples, and sociology came more and more to deal with the data of advanced peoples. This distinction, at times quite uncertain, has been the main line of cleavage between the two disciplines. Despite the European origins of the concepts of these subjects and the strong early influence of such men as Tylor and Lubbock upon anthropology in this country and of Comte and Spencer upon sociology, both of these subjects had early beginnings in the United States. The slavery controversy appears to have been very important in both cases, and in that of anthropology the Indians—still exercising their traditional customs with but little interference from white civilization—were another important factor. From the thirties to the fifties, when the slavery controversy was at its height, a very considerable literature arose in the lower South, centering around Charleston in particular, dealing with the physical anthropology and ethnology of the Negro. The southern standard periodicals, of which there were then several of

high grade, carried this discussion, and a considerable number of books were published, the more outstanding of these being J. C. Nott's *Two Lectures on the Natural History of the Caucasian and Negro Races* (1844), *Types of Mankind* (1854), *Indigenous Races of the Earth* (1857)—the last two written in collaboration with G. R. Gliddon—John Bachman's *Doctrine of Unity of the Human Race* (1850), Thomas Smyth's *The Unity of the Human Races Proved* (1850), and S. D. Baldwin's *Dominion; or The Unity and Trinity of the Human Race* (1857). These works were often very scholarly, drawing as they did upon the latest European investigations in physical anthropology, but science was also mixed inextricably with appeal to theological authority, with here and there a direct refutation of Biblical authority when it appeared to conflict with the findings of scientific investigators. Nott and Bachman, in particular, were men of learning who made some original studies in the field. The Negro question was, however, settled by war instead of by argument, and the next outstanding work in anthropology was done by L. H. Morgan in connection with his field studies of the Iroquois Indians of New York. His *Ancient Society* (1877) and his *Systems of Consanguinity* (1869) had great influence upon the development of anthropological theory throughout the world, possibly more in Europe than in America. It is now recognized that *Ancient Society* was inadequately inductive, especially in its assumptions of uniformity and universality of culture patterns, but Morgan shares with Tylor the honor of having done more than any other men to lay the foundations of cultural anthropology.

Fortunately for the future inductive development of the subject, the United States Geological Survey became interested in 1876 in studying the archaeology of the Indians and organized an ethnological survey under J. W. Powell. This work grew into the Bureau of American Ethnology, which expanded its interests to embrace the cultural aspects of the subject and resulted in a large number of field studies of great importance. The founding of the American Museum of Natural History (1869) with its close connections with the teaching of anthropology through some of its leading curators, such as Putnam, Boas and Wissler, and the organization of other museums, such as the Field and Peabody, have also contributed greatly to an inductive basis for the subject. As Wissler has pointed out, anthro-

pology was long primarily a museum and field subject instead of a college discipline. Furthermore the earlier stress in college curricula was primarily upon physical anthropology and archaeology, as it was in the museums. The first actual professorship in the subject was established at Harvard under F. W. Putnam in 1885, but it does not appear to have been active before 1887, and thereafter it developed slowly. In 1886 D. G. Brinton became professor of American archaeology and linguistics at Pennsylvania. Even today anthropology has not a very strong foothold in the universities, although it is growing rapidly. Chicago had a professor in the subject (Frederick Starr) from its opening (1892), and courses were given at Columbia from about the same time by W. Z. Ripley and F. H. Giddings, and after 1896 by Franz Boas. Under the stimulus of Stanley Hall, Clark University had been giving instruction in anthropology since the eighties, and Sumner at Yale had instituted courses in the cultural side of anthropology in 1885. But Sumner was a "book" anthropologist, and modern anthropology prides itself on being a field subject with a very accurate technique of description and analysis. Under the influence of Boas, who has dominated the teaching of the subject for a quarter of a century, analysis has been much more important than synthesis, but recently interest in synthesis and in inductive generalization has revived, especially under the leadership of Wissler, Kroeber, Goldenweiser, Tozzer, Dixon and others. Certainly the primary interest is now in cultural anthropology, and increasingly in non-material culture. Already strong departments have been established at Harvard, Chicago, Columbia, Yale and California, and there are few of the larger universities without a chair in the subject.

Perhaps the first treatise on sociology ever written was that by a Mississippian, Henry Hughes, entitled *A Treatise on Sociology, Theoretical and Applied* (1854). In 1854 also George Fitzhugh of Virginia wrote *Sociology for the South; or The Failure of Free Society*. Both of these volumes bear obvious internal indications of a theoretical reaction to Comte, and equally as obviously they reveal the slavery controversy as the immediate occasion for their production. At that time the South was in intimate contact with the main thought currents of the world. But there were also several other sources for the new subject of sociology, which began to appear in the college curricula in the seventies

and had its first outstanding literary formulation in this country in Ward's *Dynamic Sociology* in 1883. Most of these were academic, or at least systematic. Moral philosophy, which was closely related to the early development of politics and political economy, was especially antecedent to sociology. An examination of such a textbook as Combe's *Moral Philosophy* (1840), long popular in this country, or of Wayland's *Elements of Moral Science* (1835), written to replace Paley's *Principles of Moral and Political Philosophy* (1785), or Paley's work itself, reveals the fact that perhaps the larger portions of these works were sociological in fact and principle. It was only a step to the academic detachment of this material and the separate pedagogic organization of it. This step was apparently first taken definitely by Robert Hamilton Bishop at Miami University, where he gave a course in the "Philosophy of Social Relations" from 1834 to 1836. He had been trained at Edinburgh, where he may have been influenced by Chalmers, and had taught at Transylvania before going to Miami. In 1850 W. H. M'Guffey, famous for his Readers, a former associate of Bishop at Miami and then professor of moral philosophy at the University of Virginia, offered a course entitled "Philosophy of Social Relations, or Ethics of Society" and continued it until 1858. As early as 1754, however, the College of Philadelphia gave instruction in "The Ends and Uses of Society," and in 1794 the professor of Greek at Columbia College offered a course in "Humanity," the description of which reads much like the sociology of a hundred years later. The sociological character of much of the content of textbooks on classical and Jewish antiquities has already been mentioned.

But perhaps the most significant antecedent to sociology, after moral philosophy, was a new subject entitled "Social Science." The first work in this field was that by Henry C. Carey, entitled *The Principles of Social Science*, published in three rather rambling and repetitious volumes in 1858-60. Carey's object was to bring together in a single treatise a discussion of the significant factors molding society and social policy. To him these were of course largely economic, but his treatise was much more general and inclusive than a technical treatise in economics. In 1865 the American Social Science Association was organized to promote much the same synthetic viewpoint. In that year also A. L. Perry began to give

instruction in social science in his course in economics at Williams College. In 1868 R. E. Thompson, a disciple of Carey, offered an independent course in social science at Pennsylvania, and other courses were established by Sumner at Yale (1872), Laws at Missouri (1876), Mayo-Smith at Columbia (1878), Dunster at Michigan (1880) and Sanborn at Cornell (1885). Other courses followed, and in some institutions, such as Columbia, Brown and Baylor, the term still persists, although it is generally more inclusive than sociology. It has also become a generic term including all of the social sciences, a result which perhaps its early sponsors consciously desired. Most of these early courses dealt with what we now call social problems, such as race, immigration, divorce, intemperance, labor, education, poverty and crime, but Sumner and Laws used the works of Spencer as reading materials. This departure, in the trail of Spencer, was soon to prove the dominant trend in sociology. Spencer not only contributed the subject matter but he also, following Comte, gave the name which soon displaced that of social science as the specific characterization of this new movement toward a synthetic viewpoint in the generalization of social data. Perhaps this was unfortunate, for it narrowed the field of the data included in the synthesis primarily to that of anthropology.

From the seventies there were a number of more or less synthetic social science trends running largely parallel with each other for nearly two decades, destined about 1890 to unite under the single administrative leadership of sociology, at the time when this subject received academic recognition. These parallel trends were the anthropological sociology of Spencer as taught by Sumner and Laws, and later in a separate course called "Sociology" at Indiana in 1885. Until 1900 this was probably the dominant content of sociology courses. Giddings' early courses show strong traces of it, although he was also much influenced by the demographic work of C. D. Wright and by the French social psychology of the nineties. A second parallel trend was the social problems courses which grew out of the social science courses in the eighties and found final expression especially in the courses on charities and criminology, as represented by Amos G. Warner, F. H. Wines and H. M. Boies, and in the courses on labor, immigration, race and population which appeared in considerable numbers in the nineties and were usually

incorporated with sociology when departments in this subject were organized. The old subject of moral philosophy was transformed in the eighties into ethics, Christian ethics, social ethics and Christian sociology. For the most part the last three were taught in the divinity schools and the first in the new departments of philosophy, but Christian sociology was often found in the denominational colleges in the nineties, and Small began his sociological career from this point of view. Both Ely and Commons dabbled in this field in the nineties, and F. G. Peabody and Graham Taylor largely standardized it in the theological schools in the direction of social problems, later to be known as "Christian Ethics" at Union, Chicago and other seminaries. Peabody introduced it as practical ethics at Harvard in 1881, where now, as social ethics, it still divides the field with sociology. A fourth parallel was the surviving interest in the philosophy of history, which was taken over from history in one form or another by practically all of the leading theoretical sociologists of the nineties, but was gradually eliminated after 1900. As sociology stood in the standard colleges in 1900, it was very largely a synthesis of all of these contributing viewpoints as well as of some minor ones not mentioned. These were not always thoroughly assimilated one to another. They were primarily secular in viewpoint, and gave evidence of a growing interest in the study and inductive generalization of contemporaneous data and a corresponding diminution of interest in anthropological or ethnological materials. These last were now beginning to receive a separate academic integration in the degree to which sociology withdrew its interest and placed it elsewhere.

A number of other subjects, not particularly social in their original subject matter, were integrated more or less to the social disciplines in this period. This was particularly true of education, biology, geography and theology. Law, on the other hand, diminished in its social synthetic outlook during this period. Constantly it became more traditional, technical and formal, emphasizing precedent at the expense of the demands of common sense and social justice. This displacement of justice by formality was variously due to the growing uncertainty of the content of the law arising out of the accumulation of great masses of contradictory decisions; to the conflict between new times and new needs and the old content and procedures of the law; to the impact of economic

interests, desirous of maintaining a status quo or of securing special favors of interpretation, upon the legal profession and judges taken from among the lawyers; to the inertia which a highly integrated and closed system, whether legal, religious or other, is likely to acquire when it insulates itself from a functional philosophy of life and environment; and finally to the over-professionalization of the law and its isolation from the other social disciplines in the colleges. Several men of great ability perceived these evils and sought to remedy them in one way or another. Langdell's case method of teaching the law, introduced at Harvard in 1870, and adopted practically universally in the better law schools by 1900, was calculated to minimize uncertainty and to train in the inductive approach to general principles. Dudley D. Field made a long and earnest fight for codification with the same end in view, especially in the seventies and eighties. About all that was accomplished here, however, was a practical movement in the direction of uniform legislation. Something also was achieved in the direction of the simplification of procedure, in the improvement of the sources of the law, in textbook making and in instruction, and latterly in the movement for social legislation and a more ethical interpretation of evidence and of past decisions. The growth of the historical viewpoint in the law in this period was of undoubted value in stimulating a constructive criticism of legal subject matter and procedure. But at the end of the century not a great deal of progress had yet been made in the direction of an adequate socialization or humanization of the law.

Geography, as we have seen, had always maintained close contacts with the social disciplines in this country. Special textbooks began to appear in geography about 1800, Jedidiah Morse's *American Geography* (1789) and Parish's *New System of Modern Geography* (1810) being the most outstanding. About the middle of the century the subject was extended from the colleges to the public schools so largely that several public school texts of all grades appeared, including among others those by Colton, Cornell, Mitchell, Monteith and Warren. In the seventies, eighties and nineties there was an increasing emphasis upon physiography, perhaps as a result of the spread of geological instruction in the colleges; but, beginning in the eighties and nineties, there was a revival of interest in social or human geography. Pre-

viously social geography had been primarily political, with some emphasis upon anthropogeography, after the tradition of Montesquieu and Buckle. Now the maturing of economics as a subject in the colleges called for a rapid development of economic and commercial geography, which gradually expanded in the direction of a social geography descriptive of the customs and institutions of peoples. This aspect of geography was largely popularized by travel books and by geographical readers such as those by Frank G. Carpenter.

The first volume dealing with education in this country was the Rev. Samuel R. Hall's *Lectures on School-Keeping* (1829). Later in the century several universities introduced courses in the theory and practise of teaching: New York University in 1832, Brown in 1850-55, Michigan in 1860 and the University of Iowa in 1873. Iowa's was the first permanent chair and was called "Philosophy and Education." Other chairs followed: at Michigan, in the science and art of teaching, in 1879; at Wisconsin, in pedagogy, in 1881; and at North Carolina and Johns Hopkins in 1884. Teachers College was incorporated in 1889 and affiliated with Columbia in 1890. In 1920 over four hundred colleges and universities were giving courses in education for prospective teachers. In 1901 Tolman listed six courses in the sociology of education, the forerunner of modern educational sociology, which is now to be found in a very large number of colleges and universities. Furthermore the whole subject matter of education as a discipline is moving toward a social, and even a sociological emphasis, although formerly in this field the psychological emphasis was most prominent, and perhaps still is. In the theological seminary the social emphasis is also growing rapidly, until advanced institutions of this type, like Union and the University of Chicago Divinity School, are becoming largely schools of sociology, anthropology, psychology of religion, religious education and social (Christian) ethics. Ethics in the departments of philosophy is also becoming increasingly social in content.

III. THE PERIOD OF MATURATION AND SYNTHESIS. The growth of the social disciplines has been very marked since 1890. In 1884 there were about twenty full time men of professorial rank teaching history in the colleges. In 1895, according to Jameson, this number had grown to approximately one hun-

dred, almost half of whom had studied in German universities. The recent growth has also been great, but less marked relatively than that of the social sciences. Between 1876 and 1892 (16 years) courses in economics multiplied 5.8 times; between 1892 and 1910 (18 years), 8.6 times; and between 1910 and 1925 (15 years), 4.6 times. The peak of growth in this subject was apparently reached around 1900. Few departments of political science were established independent of history before 1900, those of Wisconsin and Harvard, for example, dating respectively from 1901 and 1909. In 1913 there were 336 colleges and universities, out of a total of 546 for which data were obtained, offering political science, and in thirty-eight of these there were separate departments of political science. In 1889 there were only four institutions offering sociology by name. In 1901 there were 132 institutions with 399 courses. In 1909 the number of collegiate institutions teaching sociology had increased to 337 and the number of courses to 1044, a growth of 155 percent of institutions and of 162 percent of courses in the intervening eight years. Since this period the rate of growth has probably been slower. Between 1865 and 1920 a total of 142 new law schools affiliated with other educational institutions and fifty-four independent law schools were established. Fifty-four of the former type and twenty-four of the latter ceased to operate. In 1925-26 the total number of degree conferring law schools was 168 and the total student attendance upon these was 44,273. In 1897 there were only three distinct chairs in geography, although many more men gave part of their time to the subject. In 1920, 170 colleges and universities offered geography, and in 1924 there were 494 college courses and 15,004 college students in the subject. The majority of the courses dealt primarily with human geography. The growth of other social subjects has already been noted.

Beginning with the nineties of the last century, and especially after 1900, new trends became manifest in the social disciplines. The period of experimentation in the selection of a workable method was drawing to a close, and the various fields settled down to productive work largely to the exclusion of methodological discussions. Another important trend, especially after 1900, has been that toward synthesis. The border lines between the social disciplines began to disappear and overlappings became more numerous. The problem of jurisdiction,

so absorbing in the nineties, has ceased to concern the investigator and student in any vital manner and is being left more and more to the administrator. The result is that all of the social disciplines have come to be largely synthetic, as was sociology in the last quarter of the nineteenth century. Also, there has been a marked increase of emphasis upon contemporaneous data as the subject matter of investigation in the social disciplines. This is indicative of the growing emphasis upon the use of science to interpret the world in which we live. In a static world tradition is perhaps the best interpreter, but in a highly dynamic world, like ours, contemporaneous facts and generalizations from them are necessary to give perspective and to make clear our adjustment needs. Other trends are toward practicality and the application of facts to problems, toward a growing emphasis upon professionalization and the training of experts in the social sciences, and likewise toward an increasing importance assigned to the social subjects not only in the college curricula but also in public opinion and behavior as a whole. Finally there has been a vast corresponding increase in investigation and publication, especially in recent years. All of this indicates that the social disciplines are now reaching that degree of maturity which will permit them to be characterized as sciences, and in their professionalized aspects as applied sciences.

The central phase of this struggle to become sciences has been to develop a dependable method of gathering and generalizing data. At the beginning of the nineteenth century the social disciplines, with the partial exception of law and history, were primarily social philosophies. Even in law philosophic speculation was frequently mixed with deductions from precedent and categorical dicta. Law was largely authoritarian and to a nominal degree scientific. History also largely depended upon authority for its facts and not infrequently interpreted these with an *a priori* laxity that called forth the strong disapproval of the critical historical school, whose primary concern it was to develop a method of finding and testing historical facts. Beyond the collection and evaluation of data the historians were not at first concerned. Political economy and politics were not insensitive to objective data, but the work of the classical economists and of the political philosophers gives abundant evidences that generalizations did not always await the accumulation

of large masses of verified data. Moral philosophy was professedly speculative, although it did not go so far in the disregard of observation in its preference for *a priori* logic as had its predecessor, the natural law school of philosophy. These conditions could not well have been otherwise in the first half of the nineteenth century. There had not yet been developed an inductive method for the social sciences, although the philosophers of history had attempted it and Comte and others had written about it. The leaders of the social disciplines after 1865, and especially those who had been to Germany, saw the weaknesses of the speculative approach and of the pseudo-inductive method of the philosophy of history school. To many of them it seemed that the remedy lay in the application of the critical methods of history to the other social disciplines, and for some three decades this was attempted, with the results noted in the preceding section. They did get valuable perspectives upon the origin and growth of their problems, but in a rapidly changing world such historical perspectives are inadequate guides to the present and the future. Above all, the historical method, however well tested the facts may be, does not give an adequate basis for generalizing regarding the present. In very few fields are there sufficient comparable data to afford a dependable sample for statistical generalization, and reasoning by analogy is particularly dangerous with respect to historical data, because each period of history involves different conditioning factors. The historians themselves realized this limitation and largely abstained from generalization. But the social sciences cannot be so abstemious if they are to be sciences rather than history.

The use of anthropological data for generalization, which appealed so strongly to Spencer and to Americans like Morgan, Sumner, Veblen and most of the early sociologists, proved of little more value. While these data were not taken from such a wide range of historical periods, they were abstracted from a vast number of space environments. This fact gave the anthropological or ethnological data almost as great a diversity of meaning as the dissimilarity of the time environments gave to historical data. If the anthropological data had any superiority as bases for social science generalizations it was largely due to the fact that the samples in any one field were usually more numerous. Driven largely to abandon

both of these attempts at securing an inductive basis for the social disciplines, the leaders turned with more success to the statistical method, the virtues of which had been more or less recognized throughout the century. The thing most needful in connection with this method was an abundance of facts capable of being used as samples. In vital statistics the problem of collection was solved gradually by governmental agencies. Business also was able to assemble certain types of data necessary to statistical generalization. But in some other fields the problem was not so easily solved and had to await the appearance of private endowments for the encouragement of research. Various governmental bureaus and divisions, and especially the census, have also shown a disposition in recent decades to recognize the nature of the problem involved. On the other hand, the problem of developing statistical methods, as distinguished from the collection of data to be handled statistically, is largely the task of the scholar and the methodologist. It is his task also to work out the technique of the collection and classification of data. In this connection the case method has come recently to have an increased importance. The case study has two functions. As description and analysis of a specific situation or problem it is a very old technique, known to history, medicine, law and many other fields, and it has recently been elaborated and perfected on this side into the survey, the life history, family history, etc. But there is also another function for the case analysis, that of definition and standardization of data to be used as materials for statistical generalization. The case analysis itself gives only a specific description. It can be utilized as a means to a more general and inclusive perspective only by subjecting it or its defined and standardized elements to statistical manipulation and generalization. The one method gives concreteness and the other perspective. Both are being rapidly perfected by the social sciences.

One of the most marked present trends is toward synthesis and accommodation in the social disciplines. In the nineties many leaders spoke and wrote as if they believed that the boundaries of the social subjects had been predetermined from the foundation of the world. It is doubtful if any one would do that now. The problem is the important thing today, and it is regarded as the property of any person or department that is competent or

equipped to handle it. Each of the social subjects now takes material from the others quite freely. There is no copyright on facts, but only on the organization or use made of the facts. The same intellectual need for perspective and reasonable completeness of view which brought sociology into existence is now bringing all of the social studies into a more harmonious cooperation and adjustment. The present emphases upon contemporaneity and functionality have had much to do with this synthetic trend. In a century history has completely reversed its major emphasis from ancient to modern, and even to current or contemporaneous, history. And at the same time it has expanded the range of its subject matter from politics to include all phases of human action and thought. Its content is no longer merely past politics but it includes all past social subjects. The only distinctions left between history and the other social disciplines are that it covers more than just the data of social relationships and relates to the past instead of the present. But as history comes more to emphasize the contemporaneous and resumes its old habit of generalizing, even this major distinction largely disappears.

Nor is one social science able longer to build up its data and principles without giving due regard to those of the other social disciplines. This is particularly noticeable in connection with law and religion, although excellent examples might also be taken from economics, political science or sociology, not to mention other subjects. Sociology has been compelled to give due cognizance to economic and other cultural factors in developing its findings. Economics is today in process of reorientation toward an institutional economics, because of the necessity of recognizing the findings of social psychology, sociology, politics and anthropology. Political science within two or three decades has, under the spur of economic and sociological analysis, turned from the formal analysis and history of constitutions to the study of governmental and political practices. It was E. J. James of Pennsylvania who first, in the late eighties, struck the modern practical note in political science. A. B. Hart followed at Harvard in the early nineties. His *Actual Government* (1903) has since been supplemented by many other studies, such as the works of Lowell, Beard, Brooks, Munro, Merriam, Young and Holcombe, going much farther in the same general direction. The work of Beard has been particularly outstanding for its recog-

nition of the influence of the economic factor as a psycho-social background to political motivation and action. This has also been emphasized by Merriam and his school at Chicago, and in addition this school has undertaken with success to analyze the various social and economic currents which condition public opinion. Political psychology, as a phase of social psychology, is a recognized and important phase of the science of politics in every progressive school, and it is even more a part of the general literature of the subject.

On the practical side political science has increasingly turned its attention to problems of administration and control. Goodnow and Fairlie, especially, have emphasized repeatedly in the last three decades the importance of administration, and the newer tendency in this field is to discover the practical material and psycho-social obstacles and aids to successful governmental administration. International law, once a matter largely of logic, and later of history and formal documents, has now come to be more particularly an analysis, on the one hand, of international practises and relations, including informal diplomacy, and on the other, of international opinion and affairs (primarily economic). Publication in this field is moving in the same direction. In all of the social subjects the emphasis is increasingly upon the analysis of the informal backgrounds and conditioning factors, for it is recognized that the formal relations and facts but imperfectly represent the actual situation and are usually results rather than causes. Thus economic, social and psychical factors are often of more significance as explanatory categories than is mere logic. This fact has brought the new science of social psychology into existence and has made it largely basic to all of the other social disciplines. In the new orientation of the social disciplines toward contemporaneity and synthesis it has largely taken the place of formal logic as an aid to the explanation of social processes.

Sociology and anthropology also have been greatly influenced by the other social studies. Being largely a synthetic discipline, sociology has been under the necessity of collecting for itself a body of dependable data. These have been borrowed largely from history, economics, political science, anthropology, psychology and biology. This fact has resulted in the establishment of numerous filiations between sociology and the other social subjects, which have not

infrequently eventuated into new connecting social disciplines, such as social biology, social history, social economics, social politics, social or cultural anthropology and social psychology. Thus the synthetic and largely derivative character of sociology, for which it was formerly much blamed, has proved to be one of its strongest points, enabling it to perform largely the function of filling out the unoccupied spaces between the social disciplines and thus to synthesize their methods and viewpoints. But sociology has not been alone in this work. The other social disciplines have also been active in pushing out their borders to make contacts with the other disciplines. Likewise anthropology has moved largely in the direction of sociology on the side of interpretation of its data. The result is an interesting rapprochement between the two subjects after almost a generation of increasing separation. Sociology is again drawing considerable data from the field of anthropology and is incorporating it as cultural sociology. Anthropology, on the other hand, in generalizing its cultural data finds it difficult to avoid becoming cultural sociology. The new relations between the two disciplines present an interesting academic problem in the scope of the various social sciences.

Recently law has been undergoing an evolution in the direction of a synthetic viewpoint. The historical approach to law gradually emancipated it from the condition of a closed system and demonstrated the relativity of its principles, based so largely on tradition. This made it necessary for students of law to find some sanction for it other than that of precedent. In earlier times the continental legal systems sought this wider sanction in the principles of natural law, which reduced essentially to intuitional and *a priori* judgments of justice. A similar appeal to an ethical philosophy of law was made by some of the critics of our own legal system in the second half of the nineteenth century. But it remained for a group of men who had caught the new synthetic spirit in the social sciences to see that the new sanctions of the law must be found in science instead of in philosophy. Roscoe Pound has been the leader in this reorientation of the law, which he has called the sociological theory of jurisprudence. He attributes the inspiration of his theories in large measure to his contacts with George E. Howard, E. A. Ross and A. W. Small, but the general trend of the time toward synthesis has also been largely responsible for this new

humanistic emphasis in law. As the result of a long campaign through articles, books, addresses and especially his teaching in the very influential Harvard Law School, Dean Pound has been able to popularize this viewpoint in his own generation. Harvard has furnished a very large number of the law teachers of other universities, and practically all of the recent Harvard law men are enthusiastic promulgators of the sociological theory of jurisprudence. The central conception of the theory is that law is an instrument for the better adjustment of human relations of whatever character, traditionally called into requisition when these relationships become unbearably pathological, but perhaps also to be used constructively and preventively with discrimination. Thus law is increasingly regarded as a public service rather than as merely a source of private profit. It is also recognized that law can satisfactorily perform its function of securing a normal adjustment only if it takes adequate cognizance of the social and personal factors involved in the situation, which means that the lawyer as well as the law must become increasingly informed and molded by the other sciences, and especially by the social sciences. This is essentially the synthetic viewpoint.

This viewpoint in law has made considerable headway in its academic form at Harvard, Columbia, Yale and Northwestern, and perhaps at some other institutions. Harvard has become noted for its studies in the social aspects of law. Since 1928 the Columbia Law School has been engaged in such studies as familial law (undertaken jointly by a lawyer and a sociologist), recent trends in corporate law, the psychological and logical foundations of the rules of evidence in Anglo-American law, research in the field of commercial bank credit, the administration of prosecutions in American cities and methods of formal accusation in criminal prosecutions. Thus law is making contacts with all of the social sciences. Concerning the new Institute of Human Relations at Yale, so far as it applies to law, President Hutchins of the University of Chicago and formerly dean of the Yale Law School, says: "In planning the institute we have had constantly in mind the need for the cooperation of lawyers and social scientists in the study of the group aspects of human behavior. . . . The attempt in the institute will be to study the rules of law in relation to life as it is being lived in the United States today, in the light of all the data that economists,

political scientists, psychologists and psychiatrists can bring to bear upon them." What the Yale Institute of Human Relations is expected to do for law it will also attempt to do for medicine, business, politics, etc. Nothing could be more typical of the new synthetic spirit in the social sciences than that exhibited by this new research institute at Yale. So far, however, this new sociological and humanistic jurisprudence is primarily in the research and publicity stage. It will be perhaps a generation or more before it actually transforms the teaching and the practise and the making of the law.

The trend toward professionalization in the social disciplines, noted earlier in the case of law, also began in earnest for political economy, or economics, before the close of the nineteenth century. The industrial system had reached such a degree of complexity and of perfection of technique that it was calling for experts. The Wharton School of Finance and Economy (now Finance and Commerce) of the University of Pennsylvania was the first to respond to this demand, in 1881, following the short-lived attempt at the University of Louisiana in 1849-53. Other schools of similar nature followed. The first of the state universities to institute a school of commerce of university grade was the Louisiana State University in 1899. The period after 1910 was especially prolific in the development of schools of commerce and business administration. Marshall found that 175 schools or courses (curricula) in business administration were established between 1910 and 1925. The courses in these schools have multiplied at a very rapid rate and cover a great variety of subjects, from commercial geography to factory management and air transportation. Most of these schools aim primarily at training in commercial and business technique with a fundamental informational background, but a few, of which the Harvard Graduate School of Business Administration is the most outstanding example, are interested largely or primarily in research and in a fundamental analysis of the subject matter. The field of education has also been professionalized in much the same way. In the nineties the normal schools began to become primarily institutions for the training of teachers in the technique of teaching, and soon after 1900 most of the larger universities established schools or colleges of education to carry on the same training work for the higher grade of

teachers. Later the colleges adopted the same system in so far as they were able, until now over four hundred institutions have professionalized courses for the training of teachers. The subjects thus professionalized are chiefly psychology, sociology, biology and the common school branches.

Sociology, psychology, biology and to some extent other social sciences have also been professionalized in the schools of social work. The beginnings of this movement go back to the American Social Science Association, founded in 1865 to promote the study of the social sciences and especially their application to social problems. This association furthered the organization of the National Prison Association (1870) and the National Conference of Charities and Correction (1879). This latter organization was also instrumental in the promotion of social work training. Dunster's and Sanborn's courses in social science at Michigan and Cornell in the eighties began such instruction, but largely in a theoretical way. In 1894 Ely at Wisconsin and P. W. Ayres, secretary of the Cincinnati Associated Charities, promoted a combined theory and field training scheme, but this was given up the following year. In 1898 Ayres was more successful in starting a six weeks training course for social workers through the New York Charity Organization Society. This gradually grew into the New York School of Philanthropy. In 1899 S. M. Lindsay and S. N. Patten of Pennsylvania initiated a training course within the university. Within the next decade training schools were established at Boston in connection with Simmons College and Harvard University, and at St. Louis. Thereafter the growth was more rapid, until in 1928 there were thirty-five schools of social work of college grade in the United States and Canada, thirty of which were affiliated with, or were integral parts of, universities. There was also a much larger number of colleges and universities offering part time training in social work. Professional training in political science subjects has not reached the same degree of separate development as in business and social work, although in some schools, like the Wharton at Pennsylvania, training of an effective character, especially in consular service and municipal administration, has been developed. The chief reason for the underdevelopment of professional training in political science is perhaps the "political" character of our governmental system. Journalism

has had a much larger development as a professional or vocational subject, but its trend has been primarily technological and very little toward the synthetic viewpoint of the social sciences.

The increased professionalization of the social sciences in response to the demand for technical training of various types of experts has raised some serious problems about the future of the social disciplines. Having in mind perhaps the effect of professionalization upon law, many have feared that the spread of the movement would lead to a decrease in attention to the theoretical aspects of the social sciences. This is not, perhaps, as imminent a danger as that the findings of social investigation may be perverted in behalf of the interests of the new professions and of their commercial patrons. As yet it is not possible to predict ultimate results along these lines. More optimistic social scientists point to the stimulus which industry gave to the physical and biological sciences, claiming that the same result will follow in the case of the social sciences. There is, however, a different factor involved in connection with the social sciences—the fact that they are with difficulty protected from prejudice and propaganda. For example, will the profession of advertising not only make use of the data of psychology and sociology, but also attempt through propaganda to pervert the findings of these subjects with regard to the social significance of the products or commodities advertised? Another contingency often urged is that the overemphasis of the private business man's point of view, especially in business economics, which is developed primarily in the service of private entrepreneurs, may lead to the magnification of an individualistic viewpoint and practically to the suppression of the social or public viewpoint in economics. There also seems to be some danger that the technique of administration may crowd out an adequate consideration of the wider aspects of social policy in social work and in public administration. It is always characteristic of the professional training school that it has little time for "theory" due to the heavy load of "practical" courses, and thus its technique, like that of the law, becomes an end in itself, a ritual, not subjected to criticism from within. One attempt to meet this difficulty has been the elevation of the professional schools into graduate and semi-graduate status, with the requirement of a general non-technical course as prerequisite to matriculation. This

solution is largely invalidated in many institutions by the fact that the withdrawal of most of the social disciplines into professional schools has resulted largely in returning the control of the colleges of liberal arts to the more reactionary subjects, which impose so many "requirements" that, as at the University of North Carolina, it is impossible to elect more than a smattering of the social sciences. At the University of Minnesota, for example, in 1920 a rule was passed requiring students of the prelegal course to take Latin, but giving them no opportunity to elect psychology or sociology.

We have already seen that research in the field of history was not unknown in colonial times. In the national period before 1860 a number of men, including Sparks, Clarke and Force, were able to interest the federal government in doing something toward the preservation of important documents and the publication of *Diplomatic Correspondence* (1829-30) by Sparks and *American Archives* (1837-53) by Force, and other works. We have already noted the leading histories and other writings of this early period, some of them representing trustworthy research. After 1865 the various state historical societies, especially those of Wisconsin and Massachusetts, sponsored important historical investigations. The work of Justin Winsor and R. G. Thwaites in connection with the former merits especial mention. The United States government also made collections of the Civil War records, and began to publish valuable researches in American ethnology and archaeology after 1879. The Massachusetts Bureau of Labor Statistics and the United States Bureau of Labor, the Federal Census Bureau and other governmental research and publication bureaus did increasingly important work of a social science character, especially in statistics, after the eighties. Gradually similar state bureaus fell in line and added their quota to research and publication. Especially since 1900 there has been a large expansion and a considerable improvement in the quality of the social research undertaken by federal and state departments, such as the immigration, children's, women's, agricultural, commerce, education and public health agencies. These have come increasingly under the direction of men trained in research by the universities. But governmental research in the social sciences is likely to be cast along rather general lines, with an eye to popular rather than professional consumption. It is rarely pathfinding. This latter need has been

filled by the universities as adequately as their resources would permit.

Starting in the seventies with the monographs of graduate students and the work of a few professors, usually German trained and especially interested in research, the universities expanded their research programs as their funds increased, until they came to include research fellowships and assistantships, research professorships, laboratories and publications. Chicago is now building a million dollar research laboratory for the social sciences alone and publishes more than a dozen research periodicals. Yale has just received a \$7,500,000 endowment for a research institute for the study of human relations. Columbia, Harvard and Johns Hopkins have long maintained excellent series of research publications, which several other universities have imitated in the last two or three decades. There are also almost a score of university presses designed particularly to publish research work that the commercial publishers find unprofitable or difficult to handle. Aside from these channels for research publication the various social sciences have their national professional associations, which publish journals and usually have an official annual publication besides. The Archaeological Institute of America was organized in 1879, the American Historical Association in 1884, the American Economic Association in 1885, the American Folk-Lore Society in 1888, the American Anthropological Association in 1902, the American Political Science Association in 1903, the American Sociological Society in 1905, the American Association for Labor Legislation in 1906, the American Farm Economic Association in 1909 and various other social science associations of national and local scope at earlier and later dates. According to *Bulletin No. 8* of the American Council of Learned Societies (1928), anthropology now has four standard journals, archaeology four, economics eleven, geography five, history sixty, international law and relations two, law forty-three, political science six, religion seven and sociology nine. Libraries and museums have also multiplied. Every large city in the United States now has a library supplied with hundreds of thousands of volumes, and a few of these with more than a million books. There are also forty-one university libraries possessing more than 100,000 volumes each; the libraries of California, Chicago, Cornell, Illinois, Michigan, Minnesota, Pennsylvania and Princeton have

each more than 500,000 volumes; Columbia has more than a million books, Yale approximately two million and Harvard almost three million. Working museums are practically as numerous. In addition to these agencies of research and publication various private associations and foundations, too numerous to mention in detail here but described at length by Ogg (1928), have been established since 1900. As Ogg says, we no longer suffer from a paucity of research. Our next concern is with its quality, which perhaps is as good as can be expected at the present stage of development. Another problem, which belongs less to pure science than to the applied sciences of education and administration, is that of procuring as wide a dissemination as possible of this research among the masses and its application to the solution of our social adjustment problems. There are also important problems connected with the administration of research funds and of research itself which must be worked out before research can achieve its maximum results.

The control and formulation of the social disciplines, as well as of publication, has come in recent decades to be overwhelmingly in the hands of the universities. This fact renders the organization of the universities and the relations of teachers and researchers to the institutions matters of great public moment. Salaries are probably fairly adequate at the present time, being sufficiently low to place more of a premium upon work than upon golf and social life, and not sufficiently low actually to prevent productive labor. Also, the spirit in most American universities is decidedly favorable to productive labor instead of to brilliant conversation and elegant leisure. The matter of academic freedom perhaps leaves more to be desired. Historically there have been two great obstacles to academic freedom in this country—theological and politico-economic irregularity. Cooper, one of the ablest scholars of the first half of the nineteenth century, was forced to resign from the College of South Carolina in 1834 because he would not accept the Penta-teuch. His heresy so frightened the good people everywhere that a large number of denominational colleges were established during the next two decades to compete with the state universities, and they succeeded in keeping the latter on the verge of starvation by denying them state appropriations until the new era in education in the eighties and the nineties gave them a fresh lease on life. Few professors out-

side of denominational colleges and theological seminaries are now dismissed on theological grounds, and then usually with great reluctance. Some of the more advanced seminaries even, such as Union and Chicago, now refuse to dismiss a professor on merely doctrinal grounds. Religion has come to be something more than theology and along with its socialization it has achieved a certain degree of tolerance.

On the other hand, political and economic limitations upon freedom of teaching and expression appear to have tightened. Even Jefferson felt it desirable to choose a "regular" professor of politics for his University of Virginia and carefully to supervise the political reading matter of the courses in this field. It would be impossible to include here a list of the men who have been dismissed from their academic positions because of their political and economic views in the last fifty years, but the following are rather typical. Repeatedly the protectionists attempted to oust Sumner from Yale and almost worried him into a resignation in 1880 on the charge of using Spencer's work on sociology as a text. In 1886 H. C. Adams was forced to leave Cornell at the instance of Henry Sage, who had been offended by the former's remarks on the Gould strike. In 1894 Ely was up before the trustees at Wisconsin on the charge of radicalism. In 1895 E. W. Bemis resigned from Chicago, stating that his economic views made the step necessary. The resignation of E. Benjamin Andrews from Brown in 1897 and his transfer to Nebraska in 1898 are well known, as is also the dismissal of E. A. Ross from Stanford in 1899, because of his views on the immigration question. In 1911 E. M. Banks was forced to resign at Florida because of his too liberal views with reference to the North. In 1917 William Schaper was dismissed at Minnesota after a controversy with a British subject teaching in his department (political science), and the daily papers announced soon after the close of the war that the governor of the state would in the future attend the sessions of the board of university regents to make sure that no undesirable radicals were appointed on the faculty. These instances are perhaps typical of the present trend. University administrations avoid the dismissal of men on direct political and economic grounds when possible, since such action brings unfavorable publicity and results in their institutions being boycotted by the ablest individuals. Men are much more frequently forced

out by a denial of advancement, of research funds and other aids to effective work, and by administrative discourtesy. It is impossible to estimate the number of men who are eliminated in this way, but it is unquestionably large. The Association of American University Professors has not been able to solve the problem of academic freedom, although it has ameliorated conditions. A greater need is that of an intelligent public opinion which will support the social scientist in stating his findings when they have been arrived at by scientific methods.

AARONSON, AARON (1876-1919), Palestinian agricultural pioneer and Zionist leader. An agronomist of international reputation, he obtained the collaboration of the United States Department of Agriculture in establishing in Palestine an agricultural experiment station patterned after similar American institutions, and was an active promoter of Jewish colonization in that country before the war. He saw great possibilities in the agricultural development of Palestine, and considered an agriculture diversified and adapted to the local climatic and economic conditions an essential factor in the permanent success of colonization.

The outbreak of the war put an end to his agricultural work, and after an adventurous escape from the Turkish lines Aaronson transferred his activities to helping the British win Palestine and to obtaining political recognition for the Zionist cause. He took part in the negotiations with Balfour which resulted in the famous declaration promising "Palestine as a home land for the Jews," and was a member of the Weizmann commission which went to Palestine in 1918. The restoration of peace found him making plans for putting in new crops and starting a new agriculture on a quarter of a million acres in Palestine, when suddenly his career was cut short by death in an aeroplane accident as he was flying from London to Paris.

DAVID FAIRCHILD

Consult: Fairchild, David, "The Dramatic Career of Two Plantmen" in *Journal of Heredity*, vol. x (1919) 276-80; Ormsby-Gore, W., "Aaron Aaronson" in *Zionist Review*, vol. iii (1919) 35-36.

AARUM, PETTER THORVALD (1867-1926), Norwegian economist, held several administrative positions and, after 1917, was professor of economics at the university in Oslo. His earliest writings dealt with cooperation. In his chief work *Arbeidets økonomiske værdi* (The Economic Value of Labor), published in Christiania in 1908, he follows closely the theory of marginal productivity. Developing wholly deductively the laws regarding the deter-

mination of wages in a static community, he does not enter into any discussion of the applicability of these laws to real life. Aarum revised the second edition of Aschehoug's large work on economics and in his later years wrote an economics textbook, *Læren om samfundets økonomi* (2 vols., Oslo 1924-28), the second part of which treats of the practical side of the science. This part was, however, not published until after his death, and was completed by Oskar Jaeger and Ingvar Wedervang. Aarum was the first opponent of the inflation of Norwegian currency during the war, but was not so fortunate as to win the support of the politicians. With the exception of a short article on Scandinavian economists in *Die Wirtschaftstheorie der Gegenwart* (4 vols., Vienna 1927-28, vol. i, p. 122-41) all Aarum's works are published in Norwegian.

WILHELM KEILHAU

AASEN, IVAR ANDREAS (1813-96), grammarian, folklorist and lexicographer, was born on a farm in western Norway and was largely self-educated. He showed from the first a keen interest in grammar, not only in Latin and Greek but also in the modern Scandinavian and in the dialects of Norway. He was one of the first to maintain that the local dialects of Norway were not debased and corrupted forms of Norwegian but had a continuous linguistic development from Old Norse which could be traced through recognized linguistic processes. Through the generosity of the Academy of Sciences of Trondhjem he was able to travel through Norway, particularly western Norway, gathering material in substantiation of his theory. The result of this was the *Landsmaal*, a very careful synthesis of those dialects which were recognized as purely Norwegian, and the publication of a grammar in 1848 (*Det norske Folkesprogs Grammatik*, expanded in 1864 as *Norske Grammatik*), followed by a dictionary in 1850 (*Ordbog over det norsk Folkesprog*; enlarged edition *Norsk Ordbog*, 1873). Aasen also showed the literary value of the new language in poems and stories (*Ervingen* and *Symra*).

Aasen is of great importance in the history of Norwegian nationalism. The *Landsmaal* became a cause which attracted many vigorous champions, who were quick to recognize Aasen's claim for it as the way to the development of nationality and the spread of popular education. Foremost among these were Arne Garborg, the realistic novelist and dramatist, and Aasmund Vinje, the journalist, and they became the leaders with Aasen in the long and bitter fight against the *Riksmål* (Danish with a Norwegian pronunciation) which had become the "Norwegian" language. This struggle had as its first victory the decree of the Storting in 1896 that *Landsmaal* was to be taught all children in the grade schools, and today it enjoys equal rights with the *Riksmål*. The struggle (*maalstræev*) has heightened the appreciation of the cultural value of the old Norwegian folksongs, traditions and customs, and has had a profound effect on popular education. It has raised the self-respect of the country people as perpetuators of the native Norwegian culture and has strengthened the whole nation's love for everything of pure national origin.

ABANDONMENT. *See* EXPOSURE; OLD AGE.

ABBE, ERNST (1840-1905), model employer, the son of a spinning-mill foreman. He understood in youth the hardship of a fourteen to sixteen-hour working day, and accordingly when he was an employer he could see matters through the eyes of the employed. He studied physics and became an outstanding figure in the field of optics. In the Zeiss plant at Jena, which manufactured optical instruments and employed fifteen hundred persons, he became partner and later sole owner, and introduced model working regulations. He converted it into a foundation in 1896, thus expropriating himself without compensation. Although politically a liberal he advocated restriction of the power of the employer and improvement in the legal status of the worker. He opposed welfare work as mere stage trappings. "Welfare" firms required compulsory contributions

to pension funds which, through fear of loss on discharge, increased the dependence of the employed, but Abbe established a non-contributory pension fund and even introduced a system of compensation to employees discharged through no fault of their own. He also committed his concern to a system of profit sharing (which excluded the management) and to consultation with a freely elected labor committee on all labor questions except those concerning commercial management. In 1900 he proposed to this committee that the hours of labor, which had been gradually reduced to nine, be cut to eight. The workmen agreed and tried to accomplish just as much as before, but then declared the strain too great. By Abbe's orders the former pace was resumed, and it was found that without conscious effort more work was done than formerly in a nine-hour day. This led him to his famous theory of the reduction of working hours for specialized factory labor. This theory, with the by-laws for his foundation, is to be found in his *Sozialpolitische Schriften* (vol. iii of his *Gesammelte Abhandlungen*, 3 vols., Jena 1904-06). The German shop committee law (*Betriebsrätegesetz*) of 1919 incorporates both Abbe's idea of discharge compensation and his principle that in the employment of the executive, clerical or labor force there must be no discrimination based on race, class, religion or party affiliation.

Consult: Auerbach, Felix, *Ernst Abbe* (2nd ed. Leipsic 1922), and *Das Zeisswerk und die Carl-Zeiss-Stiftung* (5th ed. Jena 1925), tr. by R. Kanthack (London 1927); Weiss, Hilde, *Abbe und Ford, kapitalistische Utopien* (Berlin 1927); Wilbrandt, Robert, *Sozialismus* (Jena 1919) p. 153-58.

ABBOT, CHARLES, BARON COLCHESTER (1757-1829), English political figure, was born at Abingdon, but later lived at Colchester. After studying at Oxford (Christ Church) he joined the bar, then turned to politics and entered the House of Commons in 1795. He showed at once that rarest qualification of the parliamentarian, an understanding of finance; he became chairman of Pitt's Finance Committee of 1797 and wrote most of its reports. In 1802 he received the office of speaker of the house, retaining it until 1817, when he became a peer. His principal parliamentary achievement was the passing in 1800 of the Census Act. He had to face strong opposition, but at a time when vague fears of overpopulation and under-subsistence were current, the importance of

having accurate facts furnished a powerful argument in his favor. The act was passed, therefore, and it was put in force the following year. Another valuable public service was the appointment of committees to report on the arrangements made in connection with temporary and expiring laws and on improved methods of making new statutes known to the public. He also reformed the system under which public accountants held custody of government funds.

W. H. DAWSON

ABBOTT, CHARLES CONRAD (1843-1919), a physician noted for his contributions to archaeology, whose name is associated with the problem of man's antiquity in America. He was connected with the Peabody Museum at Harvard, 1876-89, and was curator of archaeology in the University Museum, Philadelphia, 1889-93. About the year 1876, on his ancestral homestead near Trenton, New Jersey, he discovered stone implements in such associations as to suggest to him three culture horizons—inter-glacial man, an intermediate culture and, finally, the relatively recent pre-Columbian American Indian. These conclusions were stoutly defended in a number of publications ranging in date from 1872 to 1907. He was convinced that palaeolithic man existed in America, and carried on a sharp controversy with his opponents, leaving to others the systematic study of the site. These investigations confirmed Abbott's conception of the intermediate post-glacial horizon, which he called "the argillite culture," but did not corroborate his claims for the earlier glacial horizon. Abbott's chief contribution, therefore, was the discovery of the Trenton site, with its two culture horizons. The term "argillite culture," however, proves to have local significance only, and does not designate a continental culture horizon as Abbott assumed.

CLARK WISSLER

Important works: Primitive Industry (Salem 1881); *Ten Years' Diggings in Lenâpè Land* (Trenton 1912).

ABBOTT, FRANK FROST (1860-1924), historian and philologist, was graduated from Yale in 1882, and continued his studies at Yale, Bonn, Berlin and the American Classical School at Rome. He taught at Yale (1884-91) and also, for sixteen years, at the University of Chicago, which he helped to organize. His last professorship was at Princeton (1908-24). His

History and Description of Roman Political Institutions (Boston 1901) is still, because of its soundness and precision, a standard work. Three books of wider interest, *Society and Politics of Ancient Rome* (New York 1909), *The Common People of Ancient Rome* (New York 1911), and *Roman Politics* (Boston 1923) contain, among popular essays, the fruits of several penetrating epigraphical studies. His last work, *Municipal Administration in the Roman Empire* (Princeton 1926), written with the collaboration of Professor A. C. Johnson, was at once accepted as the outstanding work in its field. Although Professor Abbott always held chairs in the classics and devoted much of his time to the interpretation of Latin authors, his graduate courses usually lay in the field of epigraphy and history. To the great amount of excellent dissertational work done under his supervision classical studies in America owed much in enlargement, and work in every phase of Roman history much of its scope and thoroughness.

TENNEY FRANK

ABBOTT, LYMAN (1835-1922), American journalist, religious leader and writer on social problems. Abbott began studying the industrial situation in America as early as 1870; in 1876 he became associated with Henry Ward Beecher on the *Christian Union* (later the *Outlook*), and in 1881 was made editor-in-chief. This journal under his editorship was the first religious periodical of wide circulation to open its pages to a general discussion of labor problems, carried on in editorials and in contributions from such economists as R. T. Ely and such ministers as Washington Gladden. In sociology as in religion Abbott sought to maintain a middle-of-the-road position, opposing socialism but persistently arguing against laissez-faire economics. He recommended the democratization of industry, urging that the "tool-users" should become "tool-owners." The church, he believed, should interpret and state the teachings and spirit of Jesus in such a way as to show their application to industrial problems. Although editorial and pastoral duties prevented him from making thorough studies, his interest in the subject and his editorial policy were influential in creating a new attitude toward labor on the part of the churches and in developing what is called "the social gospel." Abbott's sociological interests were not confined to labor problems.

Although he discussed them less frequently, he was also concerned with other social questions.

GRANVILLE HICKS

Important works: His sociological views are found in *Christianity and Social Problems* (Boston 1897); *The Rights of Man* (Boston 1901); *The Industrial Problem* (Philadelphia 1905); *America in the Making* (New Haven 1911). *Remiscences* (Boston 1915) ch. xvii, describes the genesis of his attitude toward industry.

ABBOTT, SAMUEL WARREN (1837-1904), American vital statistician, was interested chiefly in the promotion of public health and in the compilation of comparable mortality statistics. In 1886 Abbott was elected secretary and executive officer of the reestablished Massachusetts State Board of Health, a position which he held until his death. He supervised the preparation of the annual reports of the board and edited the *Massachusetts Registry and Return of Births, Marriages and Deaths* (vols. xiv-xlix, 1886-90). These reports, together with his *Summary of the Vital Statistics of the New England States for the Year 1892* (Boston 1895) long served as models for similar statistical studies. "The Vital Statistics of Massachusetts for 1897 with a Life Table," published in the Massachusetts State Board of Health, *Annual Report* (vol. xxx, 1898, p. 799-830) and one of Abbott's most important contributions, was perhaps the first significant life table prepared in this country for the whole population of a state. Abbott was chairman of a committee on vital statistics of the American Public Health Association from 1893 to 1897, and a member of the commission appointed by the same association, in 1900, to draft suggestions for the revision of the International Classification of Causes of Death. Perhaps his best known work is *Past and Present Condition of Public Hygiene and State Medicine in the United States* (Boston 1900) published by the Statistical Association. Some of his other contributions are: "Influenza Epidemic of 1889-90" in Massachusetts State Board of Health, *Annual Report* (vol. xxi, 1889, p. 305-84); "Infant Mortality in Massachusetts" in Massachusetts Association of Boards of Health, *Journal* (vol. viii, 1898, p. 134-52); "The Decrease of Consumption in New England" in American Statistical Association, *Publications* (vol. ix, 1904-05, p. 1-20).

W. Abbott" in *Michigan Monthly Bulletin of Vital Statistics*, vol. vii (1904) 77, and in American Statistical Association, *Publications*, vol. ix (1904-05) 148-49.

ABDICATION, in earlier usages, was a technical legal word. *Abdicatio*, in Roman law, denoted the act whereby a father disowned his son, expelling him from his family or depriving him of rights of inheritance; it was also the name for the act of a magistrate in quitting office (because of unfavorable auspices or for other reasons) before the usual term had expired.

In later and present usage abdication is a word of semi-technical significance, denoting the act whereby a person in high office renounces his office, either formally or virtually. Generally the term is applied only to such an act by a "sovereign" ruler—such as an emperor, king, queen, dictator, sultan or pope—and is not used to designate a surrender of office by an elected head of a republic; thus we speak not of abdication but of resignation of office by President MacMahon of France, or President Diaz of Mexico. The term implies, moreover, that the abandonment of office is voluntary—to be distinguished from deposition or dethronement. However, in a majority of familiar instances recorded as abdications, the decision to relinquish office, though nominally spontaneous, was not actually so; the abdication being in such cases a final and formal renunciation of an authority which events beyond the control of the ruler had already taken from him. Some abdications, of course, have been apparently as free as any important decision can be. For abdications have been induced by a sovereign's weariness of rule, or by his physical ailments, or by his disgust or despondency over failure of projects upon which he had set great store. Involuntary abdications have sometimes been the results of defeat by foreign enemies, as in the case of the eighteenth century abdications of Polish kings under compulsion from Russia, Prussia and Austria, and the abdications forced upon lesser European monarchs by Napoleon, and in turn upon him by his victorious enemies in 1814 and 1815. More frequently abdications have been the consequence of domestic uprising. The abdications, in November, 1918, by Emperor William II of Germany, Emperor Charles of Austria, and the thirteen German state monarchs, were the result of both foreign defeat and domestic insurrection.

Abdication in Roman Catholic law is the

renunciation of a benefice or clerical office. The law of the Roman church lays down certain rules of abdication, such as that the renunciation of office must be voluntary, for a just cause, and made into the hands of the proper ecclesiastical superior; except that a pope, having no earthly superior, resigns his office into the hands of the cardinals.

There are no general legal principles governing the manner and conditions of abdication. The throne of England can, since the Revolution of 1688, be lawfully abdicated only with consent of Parliament. In the case of James II, Parliament after a debate comprising probably the most lengthy and learned discussion ever devoted to abdication, declared that James had, by his actions subversive of the constitution and by his flight from the kingdom, "abdicated the government" and "the throne is thereby become vacant." The House of Lords preferred to designate the king's action as a "desertion"; the Commons, however, desiring a more comprehensive term which would preclude any idea that James would be free to return to the throne, insisted upon the word "abdication," to which the Lords finally assented. Only a very few written constitutions have any reference whatever to abdication. The constitution of Spain provides that a special law is required to authorize the monarch to "abdicate the crown in favor of the heir presumptive"; and the constitution of Yugoslavia provides for succession "in case of death or abdication of the king."

Abdication in Japan has had an unusual history and significance. A general practise of retirement from active life may be traced back many centuries. After the advent of Buddhism into Japan (in the seventh century), with its practise of retirement by high priests into a life of religious contemplation, it became customary for emperors to abdicate after short reigns and retire to a monastic sort of life. By the twelfth century the custom had spread to other high governmental officers; and soon afterwards it became a practise in private life for a person in early middle age to withdraw from his business and his position as head of his family and to devote his remaining years to rest and study. The politically powerful families of Japan had encouraged the practise among sovereigns; for such families made themselves more thoroughly dominant by seeing that only young emperors reigned, and by having these abdicate before they reached an age when they might prove themselves too independent. The

effects of the early political abdications (a practise which continued until well into the nineteenth century) are revealed in the shortness of the reigns and the frequency of rule by minors in Japan.

ABDUCTION. The view that the carrying off of women was originally the general mode of obtaining wives was held by many of the earlier anthropologists, and the development of marriage institutions, as also the rule of exogamy, was traced to "marriage by capture." The theory is now discarded by most authorities. In spite of the fact that the capture of women in wars and raids is found to have been very prevalent in all parts of the world, there are strong reasons against regarding this as having ever been the usual and general mode of obtaining wives. The women so captured occupy in most instances a status different from that of regular wives. The choice of wives is largely regulated by custom, in which tribal endogamy plays hardly less important a part than clan exogamy. Marriage is, in lower cultures, frequently matrilocal, the women never leaving their clan, and their husbands joining them; and this was, in the writer's view, originally the general custom. Whenever the reverse usage obtains, some consideration is exacted before the husband is per-

mitted to remove the woman. When this is effected furtively or by violence, the proceeding is resented, both as an offense against the older usage and as an attempt to evade payment of the bride-price. Abduction is, in part, often resorted to as a means of bargaining from a coign of vantage. The removal may take place with the connivance of the woman, thus constituting elopement rather than abduction. It may be connived at, after payment has been made, by the girl's relatives, but without her consent. Genuine abduction thus merges by imperceptible degrees into the widespread usages in which simulated violence on the part of the bridegroom and his friends and resistance on the part of the bride's people form part of the marriage procedure. The violence may, with the same people, be ceremonial or real according as the bride-price has, or has not, been paid. These usages are most satisfactorily explained with reference to the change from matrilocal to patrilocal customs rather than as evidencing an original stage of marriage by capture. The abduction of women is, in lower cultures, one of the commonest causes of tribal warfare, and is often formally discountenanced on that account.

To a different class of offenses belongs the abduction of married women by a member of the same tribe, which is exceedingly prevalent in lower cultures and is commonly confounded in ethnological reports and discussions with simple adultery. But by many peoples who resent fiercely the abduction of a wife, adultery without abduction is regarded with indifference. The injury is usually held, as it was in Anglo-Saxon law, to be compensated by supplying another woman. The claim of a husband whose wife has been abducted is commonly regarded by tribal law as having lapsed after a given period, after which he is restrained from taking further steps to regain possession of her.

Attic law required the abductor of a free-born unmarried woman to marry her, as did also early Roman law. The edicts of Constantine and of Justinian, however, pronounced such marriages null and void, sanctioned revenge to the extent of homicide, and disallowed the petition of the victim in favor of the raptor. Ecclesiastical law, down to the ninth century, recognized the marriages as valid in such cases, but afterwards conformed to the Justinian code. After the twelfth century marriage was again allowed, with strict provisions to secure the freedom of action of the woman. The abduction of heiresses was very prevalent throughout the Middle Ages

and down to the eighteenth century, and early English law had mainly such cases in view. Under the Criminal Law Amendment Act, 1885, mere abduction is a felony if the victim be under sixteen; abduction with intent to seduce, if she be under eighteen, and the procuring of any female under twenty one, misdemeanors. Modern American state statutes penalize abduction generally under the same circumstances and, as far as federal law is concerned, the Mann Act may be said to operate as a restraint upon the crime.

ABEILLE, LOUIS PAUL (1719-1807), was one of the eclectic and practical publicists who served as a link between the two principal schools of French economists in the second half of the eighteenth century. He was a friend of Vincent de Gournay and when, at the instigation of the latter, the Société d'Agriculture, du Commerce, et des Arts de Bretagne was founded (1757), he became its secretary and published its *Corps d'observations* (Rennes 1761-62). His *Lettres d'un négociant sur la nature du commerce des grains* (Marseilles 1763) permits us to range him among the disciples of Quesnay. Nevertheless in his *Réflexions sur la police des grains en France et en Angleterre* (Paris 1764) he returned to a semi-neutrality between the physiocratic school and its adversaries. He frankly adhered to the former in his *Principes sur la liberté du commerce des grains* (Amsterdam 1768); but the following year he separated himself again from these doctrines, and later supported Necker's policy of regulation.

G. WEULERSSE

Consult: Weulersse, G., *Le Mouvement physiocratique en France (de 1756 à 1770)* (Paris 1910).

ABELARD, PETER (1079-1142), mediaeval philosopher, theologian and educator. Abélard, the son of an obscure Breton noble, left his home at Pallet at the age of fifteen to become a wandering scholar. He studied in Paris at the

episcopal school under William of Champeaux and soon gained so wide a reputation by the brilliance of his attack on his master's philosophy of realism that he was induced to set up a lay school. At the age of thirty-four Abélard withdrew to study theology under Anselm of Laon, and in 1118, equipped in every branch of mediaeval learning, he returned to Paris to become master of the episcopal school. His learning and brilliant dialectic, which made him famous throughout Europe, were the chief agencies in converting the episcopal school, with a few hundred pupils, into what was soon to become the University of Paris. But his career was interrupted by his love affair with his pupil Héloïse. In spite of their subsequent marriage her family vented their anger on Abélard by mutilating him. This outrage and the change in psychology which followed it, as described in his *Historia calamitatum*, led him to retire to the abbey of St. Denis. The worldly life of the monks did not suit his new mood, and he was permitted to set up a chair in one of the dependent houses of the abbey, to which his thousands of pupils followed him. Here he wrote his boldest works, *A Dialogue between a Philosopher, a Jew, and a Christian* and *Sic et non* (a collection of contradictory theological opinions). He was accused of heresy and convicted by a synod at Soissons. During the rest of his life, both while he was teaching and while he was abbot of a wild and irregular abbey on the coast of Brittany, he was harassed by enemies. After he had returned to his chair in Paris in 1136, Bernard of Clairvaux preferred a second charge of heresy against him and he was condemned at Sens. The charge, which resulted from the anger of the episcopal and monastic authorities at Abélard's claim of greater intellectual vitality in speculation, was strained and was never seriously regarded at Rome. But Abélard, broken by this last blow, retired to the abbey of Cluny and died in the following year.

The significance of Abélard in the development of European thought is found mainly in the impetus he gave to independent thinking in place of the repetition of earlier writers on theology. Of his actual contributions to thought hardly any were accepted. In his writing he was occupied entirely with theology. The little secular knowledge which he had derived in his youth from Martianus Capella or Isidore he ignored, and the condemnation for heresy prevented the use of his works by later scholars.

They are in any case chiefly concerned with refinements of theological expression. But his general trend was to make doctrine rational, and he thus anticipated later schoolmen like Aquinas. Culture was in Abélard's time too scanty to give a proper opportunity to his brilliant intellect, and his force was spent in dialectical encounters over the phrasing of theological propositions. Abélard's chief service was his unique share in the popularization of school life which led to the founding of the universities.

JOSEPH McCABE.

ABELL, ARUNAH S. (1806-88), American journalist and founder of the Baltimore *Sun*. Abell worked as compositor on a penny journal in New York City with W. M. Swain and Azariah H. Simmons. The three later moved on to Philadelphia where they established the *Public Ledger*, but it was not long before Abell decided to try his fortune in Baltimore. On May 17, 1837, he and Swain founded the Baltimore *Sun*, which was one of the early penny papers in the United States and the first in Maryland. The city then had nothing but six-cent papers, but the profound business depression then prevalent made it a bad time for starting this new venture. His paper prospered, however, and before his death he purchased "Guilford," a half-million-dollar estate near Baltimore.

Abell and Swain were supporters of the Morse "magnetic" telegraph and helped apply its uses to speedy news service. The combined circulation of the penny press in Boston, New York, Philadelphia and Baltimore was then rated at 96,000, a large figure in that day. De Tocqueville noted, when traveling in this country, that whenever a laborer, maid or truck driver had a few minutes to spare, one of these journals was likely to be found at hand. Highly sensational in their news columns, these papers—and the Baltimore *Sun* was conspicuous in

this regard—insisted that the conservative higher priced papers should subordinate partisanship to the more important function of distributing news and commenting on current events. Abell was thus a forerunner of a type of journalism which now generally prevails in the United States. However, the editors of some penny papers, notably Abell, exhibited courage and intelligence, captured new audiences, and were the greatest single force of their time in educating their readers in politics, economics and democratic processes.

ABERDEEN, EARL OF. *See* HAMILTON, GEORGE GORDON.

ABNORMAL PSYCHOLOGY is the study of mental behavior that deviates from the standard set by the normal, of whatever form and however conditioned the abnormal behavior may be. Historically the recognition of mental disorders developed a psychiatry long before psychology became an established discipline. Insanity, for instance, has always attracted attention. But psychology developed as an offshoot of philosophy concerned primarily with the nature of abstract intellectual processes, and with slight reference to the emotional basis and the types and varieties of human behavior. It was therefore only with the growth of the conception of psychology as a guide to the understanding and control of individual and social conduct that abnormal psychology came into its own. Psychiatry has now become one of its several applications, continuing to furnish abnormal psychology with important data and clues arising from clinical experience, and using in turn the psychological principles thus brought to light. Modern insight traces the play of mental abnormality in the entire range of human conduct, especially conduct of social importance.

Many significant abnormal phenomena are open to general observation. The most common is sleep, which involves a lowering and an altering of pattern of the mental activity of waking life, and which gives rise to the abnormal mental products of dreams. Familiar also

are trance, somnambulism and delirium, all of which exhibit characteristics of both dreaming and waking activity. Natural and artificial intoxication, whether in the form of stupor, agitation or ecstasy, are even more common. The search for an earthly paradise by the drug route is ancient and widespread. Equally well recognized and again occurring both spontaneously and by way of drugs, fasting or prayer, have been visions and hallucinations, or motor spasms such as the contortions of the epileptic fit or the fixed posture of the religious ascetic. The ensuing failure to recall in the normal state what was done in these conditions (amnesia), the gap or lapse in the mental life, the altered orientation or failure to recognize surroundings, the occupation with fantasies and delusions, are as striking as the original change of behavior. Possession by an alien spirit was for long the most common explanation of the changed mental condition. The belief reflected the religious doctrine of inspiration or ecstasy, or of demon possession by spirits of evil. The patient was beside himself (ecstasy); an older name for the psychiatrist was "alienist."

From such common observations can be discovered the essential respects in which the abnormal mind behaves differently from the normal. It may develop sensory disorders, including insensibility to pain; distorted sensations, such as illusory visions and voices; strange sensations from within the body; or changes of taste and mood. There may be motor symptoms—convulsions, contortions, tremors and paralyses, or inability to control muscles. A second group of symptoms consists in changes in emotional behavior, notably the dominance of anger and violence in mania. The maniac has always been the typical madman. Equally deviating from the normal are the posture and mood of depression, the immobility of despair and silent brooding. As readily observed are failures in comprehension, strange beliefs or delusions, ravings, incoherence, the mistaking of fantasy for reality—variations in the thought processes that have given to "insanity" the dominant meaning of mental disorder, which involves failure to orient, to understand and to distinguish.

The behavior of those who were plainly abnormal by constitutional defect has been equally open to common observation. The idiot is conspicuously defective; and the various types of feeble-minded, from the simpleton to the dull and stupid, have added to the picture of "not

all there." That this condition so often appeared in early childhood indicated an inherent abnormality, interfering with development. The failure of mental powers in old age has also compelled attention; while the effects of accident and of injury, particularly to the head, appeared in altered mental behavior. Thus abnormal states and abnormal persons have formed part of ordinary human experience.

Such popular knowledge influenced the developing study of the same phenomena by the more systematic procedure of science. The history of psychology is too involved and too remote for inclusion in the present discussion. It may be sufficient to indicate the several stages in the development of the modern discipline. In a sense all the life sciences had to await the illumination of the principle of evolution. Without that clue the meaning of animal behavior (including human) was ill-understood. A more direct requirement for psychology was the decipherment of the nervous system. Modern psychology is neurologically minded; but even the basis for the distinction between sensory and motor neural mechanisms was not discovered until the nineteenth century. Psychology, even when transformed from an arm-chair discipline to an experimental science, continued to focus upon the minute and elaborate mechanisms of the higher mental processes and their supports. The academic and the clinical insights were but slowly amalgamated. The fundamental importance of the emotional factors in human behavior had to make its way against the intellectualist preoccupation. The importance of growth as a process, and of the child and primitive man as authentic psychological documents, had to be recognized. The interaction of bodily and mental conditioning had to be advanced from a crude influence-of-mind-and-body relation to a significant psychogenic principle. The origin of abnormal manifestations in normal trends was gradually recognized, hard lines of separation removed and the borderland discovered; while a sounder view of the bearings of heredity and environment, dependent upon a far reaching restatement of the mechanisms of transmission, was slowly gained. As the conception that human behavior is as pervasively sociological as biological penetrated and displaced over-moralized views of conduct, human experience came to be reinterpreted, and attention to be focused upon the central problem of the composite factors of personality and their play in

human relations. This comprehensive restatement of the most fundamental problems of human life was attained, however imperfectly, almost within a single generation. Its culmination is the interpretation of the data of social psychology and of abnormal psychology from a common point of view.

The influence of the rival trends in modern psychology upon abnormal psychology and their relations to it are alike eclectic. A rigid "behaviorism" such as that advocated by Dr. J. B. Watson, which regards substantially the entire range of human reaction as the issue of conditioning, does not hesitate to draw the conclusion that abnormal behavior has the same origin. This position can be reached only by ignoring such a vast range of experience that it is hardly entitled to consideration. The attention of the older type of analytic psychology to the logical processes (and their sensory support) in intellectual activity hindered consideration of deviating types; and the experimental program, however differently oriented, followed a related tradition. The problem of Gestalt psychology lies in the same field. The emphasis upon a functional and dynamic psychology, however, was favorable to an extension of interest to the more complex integrations, including the abnormal. The stimulus to the study of abnormal states and conditions is derived largely from interests outside of, or tangential to, the standard disciplines of psychology. It arose mainly from the clinical interest in human behavior and character, owes much to medical, biological, anthropological and general "humanity" pursuits, and is specifically connected with the educational motive of control in the interests of what we now call mental hygiene. There has been continuous medical interest in the mentally abnormal, in deviation of character make-up and in the vicissitudes of human nature (for which Dessoir proposes the term *psychognosis*); and philosopher-psychologists (in France more than elsewhere) have found some confirmation and illustration of principles in the abnormal field; but for more complete development abnormal psychology had to await the convergence of these many-sided modern interests. The Freudian contribution holds the unique position of a general psychological interpretation derived from the study of abnormal phenomena. Parallel with the genetic approach studying mental origins and development, and the experimental technique determining precise relations, the abnormal had become a method

of investigation as well as a division of the phenomena of the mind.

With the conception of abnormal mental behavior established, psychiatry incorporated a psychological point of view into its analysis and technique, and insanity became a legal rather than a medical concept. Psychology and psychiatry together developed certain characteristic patterns of deviation from the normal. These concepts have been the basis of all subsequent work. Mental disturbance associated with organic lesions, loss and disorder of function, or defect, were regarded as constituting a central group of the major mental disorders. The delusions of grandeur, exuberant fantasies, incoherence, disorientation and coarse deterioration of behavior that marked general paralysis of the insane were seen to be as significant as the motor impairment that gave it its name. It was realized that paretics could be diagnosed psychically as well as physiologically, and the association of this condition with syphilitic infection placed that disease in line with allied medical findings in other fields. Symptoms came to be regarded as but clues to disease patterns of the total psychic liability in one and another type of variation. The symptoms of elation and agitation (mania) and those of depression (melancholia) were recognized as phases of the manic-depressive psychosis, one type form of mental disorder. An equally useful and comprehensive category was that of dementia praecox, the failure to continue the integrative development of youth and the tendency to splitting or division of the psychic personality. In such fashion the orientation of psychiatry became dominantly psychological.

Early in the history of abnormal psychology the functional nervous disorders moved to the foreground of consideration, not only because they furnished so large a quota of all mental maladjustment, but also because in their analysis lay the clues to mental mechanisms essential to the normal maintenance and direction of life energy. Insight into the mental mechanisms in health and disease has been one of the major cooperative contributions of psychiatry and psychology. Of the psychoneuroses thus studied, hysteria is the richest in bearing. From the ancient view (embodied in the name) of its association with feminine liability, to the modern concept of a comprehensive and variable neurosis or neurotic tendency, is a far step; the transition occurred through a repeatedly altered and slowly matured development

of the concept. Hysteria as a nervous disorder with a recognizable though protean range of symptoms, may be viewed as the manifestation, in morbid intensity, of a pervasive liability and a particular temperament. In the one aspect, it involves emotional over-excitability; and in the other a tendency to dissociation. The cruder outbreaks of angry and destructive hysterical violence, the panicky fears, the high-strung sentimentalism, the erotic excesses, even the Puritanic restraints, fall within the picture. Complex emotionalisms, from mob violence, disturbing prejudices and war hysteria to paroxysms of grief and despair and religious ecstasy, present a range of disturbances individually and socially significant. Wayward impulses, irresponsible outbreaks and deficiencies of conduct may be similarly conditioned.

Such over-emotionalism, involving rapid and large oscillations within the emotional wave, intensity, impulsiveness and instability, enters into the picture of a temperament; it is represented also in a genetic stage. A distinguished British neurologist, Dr. Core, maintains that in the pattern of their responses children are hysterical, and that primitive people show similar characteristics, though in different forms; moreover all but the most stable (or phlegmatic) when under stress incline to be hysterical. To Dr. Core the process of civilization is in part the reduction of the natural hysteria of the human race. Consistent with this interpretation is the Freudian principle of regression, which regards anger outbreaks, intensive fears, losses of emotional balance and lapses into uncontrollable impulses as regressions or relapses to behavior on a lower genetic level, in part that characteristic of the child, in part that of primitive man. The greater emotional susceptibility of women, as well as the special waywardness, vagaries and flighty, high-strung escapades of adolescence and youth, fall within the scope of this diagnosis, often well within the normal orbit, at times outside it.

The strong personal tone of the range of emotions, principally those of sex, involved in this phase of the hysterical liability is peculiarly important. Under the hysterical stress experiences are responded to dominantly for their bearing on personal esteem or disesteem; the objective attitude is weakened and life centers too vividly and too intensively around the social estimates of self. In the period of courtship and mating and in the erotic relations emotional attitudes are still more centralized. The hyster-

ically implicated functions are the fundamentally vital ones associated with the dominant urges, anchored in the less consciously controlled mechanisms. Among these the sex relations may readily become dominant.

The tendency to partitioning of the psyche or to its partial disintegration, though equally characteristic of the total hysterical liability, is less readily interpreted. It appears clearly in the more extreme cases of this neurosis, yet in others may play but a slight part in the temperamental disposition. When pronounced this tendency may lead to violent contortions, loss of consciousness, altered personality. When more partial it may induce hysterical blindness, deafness, anaesthesia or paralysis, and mimic almost any variety of disease symptom upon which the liability has been fixed by way of a psychic association. These liabilities were clearly manifested in the war neuroses, when under unbearable stresses from the menacing attack upon the danger instinct men succumbed to "shell shock." The connection between over-emotionalism personally centered and the tendency to dissociation is not clear. But it can be noted that Charcot found the most susceptible hypnotic subjects among his hysterical patients; that Janet in the same group found pronounced pseudosymptoms, sensory and motor curtailments and contractions of the ego, as well as trances and fugues; that Freud found the most elaborate examples of subconscious and fantasy manifestations and bodily symptoms of psychic origin, and that Flournoy and Morton Prince found the typical cases of multiple personality and trance utterances, from Delphic oracles to automatic writing, among similar patients. When this variety of abnormal behavior appears in its most developed form among hysterical patients, we seek a unifying concept, and perhaps find it in an emotional instability, an over-action and dissociated action of the deeper emotional mechanisms, breaking away from the higher central control.

Hysteria becomes one of the major interpretative concepts for a great variety of behavior, including episodic impulsions such as kleptomania or sex delinquencies and wayward and irresponsible conduct in general. Prejudice, riot, war and class hysteria, fanaticisms and irrational beliefs, deeply disturbing complexes, illustrate as well that when feeling runs high, reason runs low. In the Freudian incidents they induce bodily symptoms. A fertile source of hysterical complexes may be seen in the nature-

set conflict between the biologically older, deeper urges, all highly emotionalized and anchored most strongly in the vital needs, and the later evolved controls of reflection and discipline associated with the higher brain centers. The commanding role of sex in the conflict remains conspicuous and pervasive.

That other formulae redistributing life values may similarly represent other types of neurotic liability or syndromes of functional neuroses, is more than probable. Neurasthenia represents the other great division of such liability. Its nucleus is an undue sensitiveness to fatigue, an inward turned psychic attitude, a hesitant reaction, a fear ridden distress, a motor incoordination, a far reaching anxiety, a devastating depression. This presents again a consistent though variable picture and in most respects one directly contrasted with the first, the hysterical tendency making for impulsive activity, and the neurasthenic for a many-sided incapacity. Less menacing socially, neurasthenia is the more subtly disqualifying and unfitting individually, and plays havoc with the attainment of that efficient integration of instinctive urges and reflective control that enters into the standards of balanced efficiency and the ideals of mental hygiene. The psychasthenic variety of neurosis is affiliated with it but extends into the domain of elaborated systems of complex behavior. It overlaps the more serious distortions of the psychopathic personality—eccentric, exotic, strangely sensitive and yet more strangely insensitive, following recklessly a few directive urges.

The mechanisms involved in abnormal psychology have been notably developed by Freud and his followers. To accept this approach as significant and helpful does not imply a full acceptance of the doctrines of Freud; it does, however, imply a conviction that the Freudian insight is essential to abnormal psychology. We shall never return to pre-Freudian ways of thinking about human behavior, its assets and liabilities, its vicissitudes and vagaries. Among the Freudian principles is that of the importance of subconscious activities and processes representing (in Jung's view) the deeper and older, more primary and instinctive urges and action tendencies—a sort of racial repository. This subconscious type of activity is more freely expressed in fantasy-romancing, both in day-dreaming and in the dreams of sleep. It is an order of thinking which proceeds mainly by the pleasure principle and against

which the reality principle (the stress of things as they are and their recognition by reason) has to make its way. The resulting neurosis may be an escape into illness, an assumed or imposed disqualifying incapacity that makes further struggle unnecessary; or it may be an irresistible fixation to which Freud assigns a sex bearing. Owing to the same conflict repression occurs, and the unpleasant and upsetting is buried alive and continues to trouble. The psychoanalyst attempts to bring these disturbing memories to the open forum of the conscious, where they may be set in order and dismissed. Inducements to neuroses may be found in early childhood incidents, upsetting shocks, sexual in most cases, by way of a trauma or psychic assault that leaves a functional scar. Conflict, especially between the powerful native urges and their social repression, is the essence of the situation.

The taboos that operate most intensively are those surrounding sex. Making sex central, Freud evolved his "family romance," in which the child-parent relation is the crux of the (potentially) neurotic situation. In one form it becomes the Oedipus complex in which the son with his emotions fixated erotically upon the mother develops a usurping jealousy of the father. The interpreting mechanism is that of symbolism. Accordingly dreams have on the one hand a patent content, and on the other hand a latent meaning which is the symbolically disguised real meaning, to be interpreted by analysis.

Another mechanism is compensation, by which, in dream and fantasy or delusive belief, the subject finds compensation for his defects by resorting to an unreal world of self-gratification. The great variety of cultural myths and traditional fairy tales are explained by reference to the same principle. They thus become racial or folklore versions of the same theme—the insistent struggle for a fuller, richer life, more abundantly or more freely satisfying the vital urges. The mechanism of rationalization also enters the picture, cloaking in the consolations of reason the repressed or unsatisfied desires of a thwarted life.

This selection of Freudian principles and mechanisms may serve to indicate the mode of approach and the positions reached by the school. The method and the conclusions apply to behavior patterns and to personalities. Much of the doctrine is summarized in the term "complex," meaning a set of ideas (on the will

side a "wish," on the sensation or action side an impulsion or impediment of behavior) highly charged with emotion, that checks or warps the natural and effective relation between stimulus and response. Complexes condition neuroses and reveal their points of origin.

In its bearing on personality, analysis as developed by Jung has led to the recognition of the two dominant types of extravert and introvert. The extravert is the more common type, with his main psychic energies directed outward to the world of things, occupations and objective interests, and but little troubled by inner reflections, doubts or emotional resistances. The psychic energy flows freely into channels of momentary occupation and is likely to be abundant, bubbling, enthusiastic. Jung recognizes several sub-varieties distinguishable as the dominant trend is modified by sensory, motor or reflective interests. He applies the same system of detailed classification to the introvert. The introvert stands closer to the neurotic source. In him the flow of psychic energy meets with resistance, with the inhibition of hesitant motor impulses, of timid withdrawal or troubled reflection. The psychic energy is directed inwardly instead of going out to objects and active pursuits. Naturally he is a more complicated individual, largely by reason of emotional complication; his aspirations may run higher, his feelings deeper, his patterns of behavior may be more intricate. For one marked introvert, there are a score mildly and irregularly introvert. Indeed every individual must be equipped with extraverting and introverting trends; but except in the very weakly toned and neutral nondescripts, there still remains a dominant type pattern.

Kretschmer makes a similar differentiation of personality types from the side of clinical experience and bodily build. He puts the question: If you succumbed to a mental disorder (for whatever reason, by inherent frailty of constitution or excessive stress of circumstance or both), what type of abnormal pattern would your neurosis or psychosis take? In the answer you will find your psychic type. On the one hand stand the manic-depressive psychoses, with their large and typically alternating fluctuations of mood (cycloids). The other statistically large component among cases of mental disorder is that of dementia praecox (schizophrenia), in which the distinctive tendency is that of dissociation or a split personality (schizoids). Naturally there are as many exceptions

as conformities, and these Kretschmer calls the dysplastic types. He makes much of the temperamental equivalents among normal people (cyclothymes and schizothymes), thereby justifying his findings as a contribution to the psychology of character analysis. His investigations associate psychic with physical types. The pyknic (robust, stocky) bodily constitution is far more abundant among those of cycloid psychic disposition; the schizoid disposition is found most typically in the asthenic constitution and in the athletic.

Parallel with the insight into the determination of behavior from above through the psychic mechanisms (notably the Freudian ones) has come equally novel and convincing evidence of the influence from below, principally through the glands of internal secretion (endocrines). The one may be termed the psychogenic, the other the physiogenic principle. Normal and abnormal behavior alike are subject to both sets of determination. It has been suggested that each of us is a physio-chemical as well as a psycho-sociological-historical person, and that the resulting personality complex is in no small measure the expression of glandular balance, dominance or deficiency.

The specific evidence is too detailed for discussion here. It is sufficient to refer to the thyroid, the "miracle gland," extracts from which, when administered to feeble-minded cretins, in favorable cases have accomplished their approximate restoration to normality; or to recall that over-excitability of the hysterical order is definitely connected with over-activity of the thyroid, and phlegmatic apathy with its under-activity (again in certain orders of cases); that the mechanisms by which active secretion of the adrenal glands occurs in violent emotional states (anger and fear) have been established; that the pituitary gland is closely associated with the determinants of bodily growth; or that the profound influence of sexual urges on behavior is again a glandular function of a different order. From such conclusions may arise a future chemistry of temperament, regulating alike normal and abnormal behavior.

Significant in this contribution is the close connection of so many of these glandular processes with the functions of the autonomic nervous system. This structure, by far the older in evolutionary terms, becomes the regulator of the vital, life shaping reactions; while the later superimposed central nervous system represents the higher level of conscious, rationalized

control. Not a little of the conflict of which life consists, and which under undue stress precipitates mental disorder, may be referred to the antagonism, the imperfect adjustment, of these two systems. Modern civilization in increasing measure makes difficult demands upon the central nervous system, while the older aboriginal urges must still be satisfied. The total nervous equipment was evolved to meet far simpler conditions, and the resulting strain expresses itself in the marked increase of mental disorder and disqualification.

The social applications of abnormal psychology may best be approached by way of child psychology. That the imbecile remained permanently in a childish state of mind was recognized of old. The picture of mental deficiency is that of arrested development, nor is it in any way accidental that Binet arrived at the concept of mental age through the practical problem of separating the subnormal pupils in the school population. By projecting the concept of retardation backward, one reaches a definition of the imbecile (mental age from three to seven) and the idiot (mental age below three years). From the more useful statement of mental age in terms of the intelligence quotient (I.Q.) is derived the category of the feeble-minded, indicated by an I.Q. of less than 70. This group may be subdivided into morons (I.Q. 70 to 50), imbeciles (50 to 25) and idiots (below 25). Except for a percentage, small but not negligible, of cases of arrested development due to disease and other causes, the mental defectives express a hereditary defect. This means mainly (as Dr. Myerson has shown) that some types of feeble-mindedness run in families; but other causes (notably syphilis), and the spontaneous occurrence of feeble-mindedness in almost any grade of human stock, must be clearly recognized. With some exceptions the individual I.Q. remains constant throughout life, so that the grade of intelligence as thus tested is of fundamental importance in the personal data of any case of social delinquency or maladjustment. Following the same procedure, it becomes possible to determine superior intelligence.

But more consequential is the study of the symptoms of "nervousness" in children and the inclusion of the maladjusted child in the program of abnormal psychology. When Dr. Cameron enumerated as signs of nervousness in young children poor sleep, irregular feeding habits (refusal of food, food resistance, food

whims, vomiting), habit spasms (finger sucking, twitchings, later stammering), negativism or the persistent "no" habit, and contrary patterns of reaction; and when he added that childhood constitutes a distinctively "nervous" or emotionally sensitive period notably characterized by tendencies to emotional upset, anger states (tantrums) and fear states (night terrors, imaginative dreads, panicky fears and violent disgusts) he outlined a program of interpretation that in its subsequent development has completely revolutionized the neurological direction of early childhood. It has shifted the interpretation of child behavior from that of naughtiness or moral transgression to that of a neurological difficulty. This contribution from the abnormal side has been of far reaching consequence in indicating the essential problems of child growth or maturing. It underlies the program of the nursery school; it continues in the free methods of progressive education. It introduces a different perspective of values, of what is important and what secondary, in the early educational process. It gives hope that later neurotic disaster may be avoided by wiser adaptation of training to the individual needs of children according to their psychological types. The whole technique of modern child study, which extends from the feeble-minded to the gifted or superior children, is strongly influenced by the clinical attitude developed in the observation of symptoms in abnormal children.

The same interest has made central the matter of adjustment; for the abnormal child is frequently the maladjusted child. Environmental maladjustments or errors in management affect most disastrously the sensitive, nervous types of children. The chief obstacle to successful adjustment is some form of nervous instability. The two rubrics of the unstable individuals and the maladjusted individuals grow in complication when the child becomes the adolescent. Not only does this deeply organic reconstruction place increasing stresses upon nervous instability, but it increases the need of adequate outlets for the more complex and compelling urges. It is the failure in such adjustment that brings to the fore the problems of unhappiness or of delinquency. Misconduct takes the direction of destructiveness, mischief making, wilfulness, truancy, vagrancy, stealing, cheating, lying, cruelty or sex offenses. The conclusion derived from clinical experience is that such forms of behavior grow out of conflict situations deeply anchored in instability of

a neurotic type and out of a maladjustment within the family or in the social stresses and imposed restraints.

A normal intellectual life, establishing right contacts with knowledge and control led by reason; a normal emotional life with proper outlets for sympathy, cooperation, generosity, fair play and control of fears and angers; a normal social life with the stimulations of companionability, consideration and respect, and the reciprocal attraction of the sexes; such is the warrant of a normal development. Upon such a diagnosis most remedial policies are based. The remedial agency is often the social worker. The foundation of mental clinics in association with schools, social aid organizations, courts, churches, special foundations, also represents the practical recognition of findings in abnormal psychology. Diagnosis usually utilizes the genetic method; it is realized that the early environment gives way in importance to the maturing environment, and that simpler impulses are overlaid by later complications. The imperfect overcoming of early tendencies, a variety of mental infantilism, may create difficulties leading to delinquency or to psychic impediments. The becoming emotionally as well as intellectually adult, the finding oneself in work, in serious purpose, in play, in the love life, in the total social adjustment of interests and pursuits—this maturing process is the difficult achievement, and marked defects in it appear as abnormal behavior.

One of the more socially important phases of such abnormal behavior is criminal activity, and among the applications of abnormal psychology, criminal psychology offers peculiarly complex problems. The central consideration is that of the psychology of the criminal, including the causes of crime. Quite distinct in scope and application is the psychology of "criminal" procedure, including that of evidence, detection of crime, the setting of the trial, the function of judge, jury and witnesses, the role of prejudice, public opinion, etc. A third field is the psychology of punishment and reform. All have been profoundly affected by the advances in abnormal psychology.

The present discussion must be limited to the more intimate phases of the psychology of the criminal and the orders of crime. The divergence of opinions in regard to the dominant causes (including motives and urges) of criminal behavior indicates the issues. Crime is a socio-legal term; the behavior patterns that it

implies are patho-psychological products. From the point of view of abnormal psychology the latter concept must dominate. There are well recognized (abnormal) tendencies to deviating behavior; under certain circumstances phases of such deviating behavior become criminal. There is no independent psychology of criminal behavior apart from deviating behavior. Even the social notoriety or prestige of law breaking as a feat of adventure and defiance finds its parallel in similar lures of social display, just as in the opposed emotional reaction the sense of disgrace and the social stigma of the trial and the prison have their counterparts in the social disapproval attaching to a large variety of (moral or conventional) misconduct or even misfortune.

The orders of crime likewise refer back to the same psychological sources. At the simplest these may be classified as crimes of malice (15 percent), crimes of acquisition (75 percent) and crimes of lust (10 percent). (The numbers are derived from one group of English statistics and are typical of their relative occurrence.) This does not mean that the tendencies to anger, to amass property, to indulge in sex passion are the most unruly trends in human nature, or the most deleterious to social welfare, but only that in certain of their expressions they come in conflict with the common good. It means that basic to such conduct when it is "criminally" exhibited are fundamental human urges shared by all, which if properly directed contribute to human welfare and happiness; it means that because these urges are strong and uncertainly poised, they are apt to be overdone and go wrong; it likewise means that the complex organization of the social environment as we know it and as we have helped to make it offers special inducements to the excessive and distorted expressions of such urges. It means that psychological defect, such as mental deficiency and still more decisively defective emotional control, is the basic "cause" of crime in at least a considerable group of so-called criminals.

If we take the next step and ask how far original constitutional deviation is the responsible factor, and how far the environmental stress, we enter the controversial field. The most definite expression of the first appears in the views of Schlapp and Smith (*The New Criminology*, New York 1928) who hold that an unbalanced glandular action is the determining factor. In this revised sense the criminal

is predominately born and not made. The evidence of such glandular origin of psychopathic deviation responsible for crime is comprehensive. The overactivity of the thyroid intensifies the urges and diminishes control; its underactivity is related to the low grade mentality conducive to crime. The relation of kleptomania to sexual periodicity in women is well established. In many respects the thesis is supported that so far as disordered emotions are due to defective human chemistry, criminal emotionalism becomes one form of expression of emotional unhealth. The same order of social temptation surrounds a considerable proportion of the community; those who succumb to crime (no differently from those who develop psychoneuroses) do so because they belong to the constitutionally deficient type of one order or another, intellectual, emotional, generally psychopathic. Superiority may have a similar basis; nor is the psychoneurotic disposition without its (at times significant) compensations. So far as such neurotic disposition is explicable in glandular terms, the argument may take that form.

Those who find the Freudian clue adequate and enlightening in regard to the causation (or motivation) scheme of deviating behavior generally, and of the psychoneuroses more particularly, are prepared to extend that application to the psychology of misconduct and specifically to the varieties of misconduct recognized as, or associated with, crime. They find the decisive factor in a strong and disturbing mental and emotional conflict. Such conflicts in turn have a setting in human relations, as well as in psychic and organic urges. Family conflicts, adolescent cravings, the emergence of sex as the usurping emotion, over-repression, protests against deprivation or inferiority feelings, present the setting in which truancy, delinquency, lying, stealing and irregular sex practises find their motivation patterns. The diagnosis is completed by the further idea that crime is at times the surrogate or substitutional escape of emotions aroused by a conflict situation, and that the crime represents a false solution of a trying situation (as do neuroses likewise). This view recognizes the neurotic dispositional factor, alike in defective mentality and in imperfect or mis-trained emotional control. It places maladjustment, delinquency and crime in the allied groups of deviating behavior with a closely related diagnosis. Accordingly, while stealing or breaking in or a hold-up constitutes the

crime, the true situation is the resort to stealing for social or personal display, for indulgence, for excitement, for revenge. Shoplifting by girls and freight car looting by boys, exploiting sex allure by women and hold-ups or forgery by men, register behavior patterns consistent with the psychology of male and female traits. Their treatment must follow the same psychological clues. Reform becomes a problem in readjustment. Complicated by different psychopathic deviations, similar psychic situations may result in different orders of crime. What is done is less significant than the source of the urge and motive. Consistent with this view is the predominating juvenile character of so large a proportion of all crimes. That there are from five to ten times as many male offenders as female is likewise an important part of the problem. The clues to their comprehension are psychological.

Those who emphasize the environmental factor do so for a variety of reasons. The extreme position is that of the "behaviorist" who regards all behavior, desirable and undesirable, as the result of conditioning systematized into training, and asserts that a proper environment and training will produce from any given human material not markedly defective to begin with, a worthy, efficient, industrious citizen in any profession. Criminals are held to be completely made by their conditions. This view comes into such gross contradiction with experience that it can hardly be accepted. But convincing evidence of the environmental factor in producing crime comes from the clinical records in the readjustment of delinquents and young offenders, from the recent experiences in humane and educative prison discipline and from a variety of sociological studies. Its great importance, which it shares with the emphasis upon favored disposition, lies in its bearing upon the methods of treatment and reform; in time it may completely transform the penal code and the false psychology and consequent sociology upon which penal traditions are based.

Yet these psychological principles cannot be indiscriminately applied. Socially and statistically a career of crime may follow upon quite the same order of deliberate and rationalized plan as is involved in ordinary honest pursuits. Low standards of behavior and temptation abound. Shady transactions, skirmishing just within the pale of the law, and occasional encroachments beyond it are common failings. Any adequate survey of crime leaves in doubt

how much of it is of psychopathic origin. Institutional statistics may place it as low as from 7 percent to 10 percent if a marked psychopathic standard is insisted upon and as high as 50 percent if any measure of mental defect and emotional abnormality is a sufficient warrant for inclusion in this class. The crimes associated with mental defect are of one order; there are other crimes, like embezzlement, that are definitely crimes of intelligence. By reason of these complications the analysis of crime must remain largely a sociological study, however much guided by the findings of abnormal psychology.

The social menace of abnormal states and conditions invades every occupation and profession. Its civic importance was brought forward by the mobilization of the Great War, with the numerous rejections on the basis of mental unfitness among the enlisted soldiers. The records of shell shock and the necessity of maintaining psychiatric divisions behind the lines; and the foundation after the war of hospitals for rehabilitation of veterans, brought vividly to the fore a suggestive picture of the widespread incapacity in the industrial and social world caused by mental disqualification.

The constructive ideal becomes the program of mental hygiene; and the recognition of the importance of this completely modern discipline itself summarizes the achievements of abnormal psychology. The normal assets of a well-integrated, well-rounded personality appear as resulting from wholesome development of a stable nervous control and a satisfactory adjustment to the conditions and decisions of which life consists; the liabilities appear in the deficits, the impediments, the handicaps of abnormal attitudes, in the lack of balance between contending urges, in weakened or disorganized controls. Sanity becomes a more distinctive concept, a more exacting ideal, by virtue of the expansion of the older limited concept of insanity, as applying to profoundly altered mental conditions, into the concept of mental deviation and deficit. There are levels of mental efficiency, of competent adjustment, of successful life management, if not of sanity, that are of high social moment. The efficient control of the mental resources of a people, the maintenance of high standards of mental hygiene, are as vital to national welfare as any contributing factor to human progress.

ABOLITION. The history of the movement for the abolition of the institution of slavery and the traffic in slaves is at once a study of the forces behind an organized movement and of the machinery for effectively influencing humanitarian sentiment and political opinion.

Opposition to slavery arose with the beginning of the Atlantic slave trade. The zeal of missionary orders, closer economic relations with the Negro and a changing European *Zeitgeist* made possible the growth of the cult of "the noble savage." During the eighteenth century this curious and friendly attitude toward non-Europeans was incorporated in the literatures of the maritime nations (*Robinson Crusoe*, for example), thus preparing the popular mind for the reception of antislavery ideas. Particularly in England after 1725, philosophical deism and evangelical piety rivaled each other in helping to swell the body of humanitarian feeling. A rapidly growing slave system, however, seemed to mock the dreams of reformers. Such conditions made inevitable a conflict between slavery and humanitarianism.

The first important direct attack on modern Negro slavery was made by an evangelical, Granville Sharp, who in 1771 and 1772 brought a Negro named Somerset before Judge Mansfield. Hargrave, the attorney for Somerset,

argued that the rules of the vanished villeinage, the only possible legal basis for the existence of slavery in England, actually did not tolerate but destroyed it. The decision, incorporating this point of view, resulted in the liberation in England of 14,000 or 15,000 slaves, valued at about £50 each. A similar decision, in the Joseph Knight case in Scotland (1778), completed the process of emancipation in Great Britain. Sharp's efforts to secure Negro freedom in the British colonies by extending these judicial decisions, on the ground that slavery was "absolutely contrary to the laws of reason and equity, as well as the laws of God," were unavailing, because colonial slavery, having the sanction of positive law, could be abolished only by legislation.

The legislative attack began after the American Revolution under the leadership of Thomas Clarkson, William Wilberforce and the younger Pitt. Their plan was not to molest the institution of slavery but to attack the slave trade. This end was to be obtained by laws against the traffic in each country and by international agreement for their enforcement. Sharp wished to abolish slavery as well as the slave trade, but the other eleven members of the Abolition Committee, organized in 1787, were convinced that the destruction of a traffic which sometimes carried as many as 100,000 Negroes across the Atlantic in one year and which yielded an average annual net income of 24 percent, was a sufficiently large undertaking. Emancipation would necessitate overriding the irritable British colonial legislatures, like that of Jamaica, whereas the slave trade could be outlawed by Parliament. Moreover the French Revolution destroyed the hope of early abolition by England alone or in agreement with other powers, threw the slave trade more largely into British hands, and caused the temporary emancipation (1784-1802) of the slaves in the French colonies, largely in order to make these colonies valueless for the English, who were then engaged in their conquest. Eventually selfish economic interests inspired some of the British planters to vote for abolition, since they did not wish the former French, Dutch, Spanish and Portuguese colonies to be well stocked with slaves if they should be returned to their original owners. In 1806-07 a new and more zealous minister, Charles James Fox, was able to secure the abolition of the slave traffic.

In the United States the twenty-year period for carrying on the slave trade which had been

granted by the constitution ended on January 1, 1808. Slavery had been rapidly disappearing in the northern states for economic reasons, and until 1807 the controversy in the United States was mild in comparison with that in England and France.

In America (1696) and in England (1727) the Quakers had been the first organized body to condemn the slave trade. Two American Quakers, John Woolman (1720-72) and Anthony Benezet (1713-84), the latter a correspondent of Sharp and a medium of information for Clarkson, were of international importance. The first European state to abolish the slave trade, however, was Denmark, which in 1792 prohibited the importation of slaves to its own possessions; this decree was made effective in 1803.

The fundamental problem concerning the means whereby abolition was to be made universal and effective continued to vex the English abolitionists. The African Institution was organized in 1807 to replace the old Abolition Society of 1787. The primary objects of the new organization were to watch over slave traders, to procure abolition in other countries and to promote the civilization of Africa by missionary enterprise and by commerce. The destruction of the traffic would, it was hoped, ameliorate the lot of the slaves in the West Indies and make possible the economic development of Africa.

The immediate task, however, was to lay plans for universal abolition at the end of the Napoleonic wars. Lord Castlereagh, who had voted against British abolition on the ground that the act could not be enforced, devoted his years at the Foreign Office (1812-22) to securing universal outlawry of the traffic in slaves. Other British foreign secretaries applied themselves to the same problem with the result that between the end of the Napoleonic wars and the Webster-Ashburton Treaty (1842) the slave trade was put under the ban of the civilized world, and machinery for its suppression, such as the mutual right of search, cruising squadrons and mixed commissions, was established.

Nevertheless, because of the great demand for slaves in Brazil, Cuba and the United States, universal outlawry and all the means of law enforcement could not prevent the Atlantic slave trade from reaching its height between 1830 and 1860. This was largely due to the increased market for cotton, coffee, sugar and other tropical products. Smuggling to the

British colonies was checked by a registry of slaves before the death of Castlereagh in 1822, but elsewhere the illicit trade flourished. British antislavery propagandists saw that slavery would have to be abolished not only as an evil in itself but in order to make the abolition of the trade effective. Accordingly in 1823 an Anti-Slavery Society was organized to effect the gradual emancipation of the slaves in the British colonies. After a bitter ten-year struggle, under the leadership of Thomas Fowell Buxton and Zachary Macaulay, a measure favoring British emancipation, including a four and a six year period of apprenticeship, became law in 1833. This victory was partly due to the fact that British slavery had become unprofitable. The British Empire was expanding its trade in the temperate zones and in Asia. The East Indian interests helped in the attack on the West Indian sugar monopoly in England and joined in the antislavery cry. To establish emancipation it was necessary for the British government to offer only £20,000,000 as partial compensation to the financially embarrassed colonial interests smarting under the blows of the humanitarian attack. Neither the warning example of Haiti nor the possibility that the sugar colonies might be completely ruined was sufficient to stop the antislavery movement.

To secure universal emancipation, obviously the next step, the British and Foreign Anti-Slavery Society was organized in 1839. It has been active ever since. Throughout the entire history of the abolition movement the chief influences in forming abolitionist sentiment in other countries had emanated from England. Now the new society applied itself to its missionary task with redoubled fervor and administrative competence. It summoned two international antislavery conventions in 1840 and 1843, in both of which American abolitionists were greatly interested.

In spite of sporadic beginnings in the eighteenth century and such attempts in the first decades of the nineteenth century as the formation of the American Colonization Society in 1816, abolition did not become a serious problem in the United States until 1831. In that year the South was alarmed by the defeat, by only one vote, of a bill in the Virginia senate to colonize free blacks and thereby encourage private emancipation of slaves. Even more disturbing was the unyielding tone of William Lloyd Garrison's *Liberator*, first published in 1831. With a passionate conviction Garrison denounced

the conspiracy of silence about the institution of slavery, and insisted on being heard. He had to contend against indifference, antipathy to the blacks, belief in moderation, the fear of disturbing the delicate status quo and especially the economic dependence of the North on southern cotton. Historical opinions differ as to the wisdom of Garrison's extremist stand, but there can be no question that he did manage to attract attention to the slave problem. In 1832 the New England Anti-Slavery Society was organized, and the next year the American Anti-Slavery Society was formed under the presidency of Arthur Tappan, with Garrison as one of the secretaries. Their members were extremely effective in organizing abolitionist sentiment and bringing the whole issue unpleasantly to the fore. They invaded the church, the college and the law court; they used the lecture platform, the public meeting and the political party; they spread antislavery literature even in the South. They had adherents as respectable as Wendell Phillips, John Greenleaf Whittier, Lewis Tappan, Edmund Quincy, Joshua Leavitt, William Jay, James G. Birney, William Goodell and Amos Phelps; in Congress John Quincy Adams presented their petitions in spite of the opposition in the South. The killing of Elijah P. Lovejoy in 1837 because of his antislavery utterances intensified the abolitionist feeling. The growing tendency of Garrison to fight for causes other than antislavery, such as woman's rights and non-resistance, produced an antislavery split in 1840. Garrison and his followers believed that both the churches and the Union were in the hands of the slave power and they were ready to break up the Union. The Tappans, the Beechers, Joshua Leavitt and their followers believed that the churches and the Union could be used to destroy slavery. One group opposed political action; the other favored it.

The problem of the annexation of Texas was made a test case by the antislavery forces on both sides of the Atlantic. The war with Mexico, the annexation of the new territory in the Southwest, and the passage of the Fugitive Slave Law (1850) alarmed the abolitionists and directed their energy even more intensely into the channels of press propaganda. A realignment of sections on the basis of the nascent industrialism brought the Northwest and the East together. The political evidence of this realignment was the organization of the Republican party between 1854 and 1860 with its program of high tariff, free homesteads, a friendly

attitude toward immigrants, and the non-extension of slavery. This constituted notice to the South that its economic and political life in the new industrial age would be circumscribed. The Republican victory in 1860, the secession of the South and the emancipation of the slaves as a war measure are part of the well-known story of slavery in America. The decade of the fifties had witnessed the education of the North in the Unionist sentiments of Daniel Webster, at the same time that the fictional propaganda of *Uncle Tom's Cabin*, the story of "Bleeding Kansas," the Dred Scott decision and Helper's *Impending Crisis* had destroyed the possibility of further compromise with the South.

Some nations had emancipated their slaves before the Civil War, others followed later. Mexico freed her slaves in 1829, and various provisions for emancipation were made by Argentina, Colombia and other Latin American states. Slaves in the Danish and French colonies were emancipated in 1848 and in the Dutch colonies in 1863; Cuban slavery disappeared under the act of 1870 providing for general freedom; Portuguese slavery was abolished in 1878; and freedom in Brazil was decreed by an act of 1888. Moreover from 1861 to 1865 British abolitionists were almost as much interested in the abolition of Russian serfdom as in the freeing of the American slaves.

The approaching end of slavery in the Americas made possible the opening up of Africa as contemplated by Clarkson, Wilberforce and Pitt. Their chief purpose had been to stop the slave trade so that Africa might enjoy an orderly economic development, but success was slow. The colonization of Sierra Leone was relatively a failure; Buxton's Niger expedition of 1840 came to a sad end. Africa remained practically unknown to Europeans, although the French established themselves in Algiers in 1830 and the British were in possession of the Cape of Good Hope. After 1850 missionaries and explorers, Livingstone among them, began to penetrate into Africa. With the development of European imperialism about 1870 the scramble for the complete partition of Africa was intensified. It continued in the readjustments of territory after the Great War. An increasing demand for African products has brought the dark continent into the stream of the world's economic life but has left the problem of the protection of the natives as a task for enlightened world opinion and governmental administration by the European powers. The relative ease with which

the Negro can be subjected to forced labor makes it possible that Africa may even now become a land of peons. The Anti-Slavery and Aborigines Protection Society and similar organizations elsewhere are therefore constantly active in bringing pressure to bear on their own governments and at Geneva to secure conventions giving colored men the maximum amount of protection against exploitation, and to assure their advancement in civilization.

Abolition has been in the past applied mainly to the attitude which aims to stamp out slavery and, by an extension of meaning, serfdom or forced labor. As applied to slavery it has meant at different times and in different contexts a program ranging all the way from the desire merely for gradual manumission of slaves to the complete and immediate extirpation of slavery as an institution. Within these extremes there have been such gradations as plans for the colonization of free blacks, or the redemption and colonization of slaves, or the outlawry of the slave traffic. Among abolitionists there has been uniformity neither of program nor of temper; extremists and pragmatists have mingled their counsels; and it is a testimony to the underlying community of purpose in the New England Anti-Slavery Society that it was able to keep together members as moderate as Samuel May and as uncompromising as Garrison.

ABORTION is the practise of giving birth to the foetus before it has become a viable human being, which is twenty-six weeks after conception. Legally miscarriage is understood to mean the same thing. The practise existed in historic times and with some exceptions is fairly evenly distributed all over the world. Plato and Aristotle approved of it, Aristotle looking at it from the standpoint of a Malthusian check on population. Hippocrates, on the other hand, referred to it in his famous oath in these words: "I will not give to a woman a pessary to produce abortion." Seneca thought it immoral but not a criminal act, while Cicero spoke approvingly of a case in Miletus where a woman was put to death for practising abortion. She had, he said, robbed the father of his hope and of the memory of his name, destroyed the support of the family, deprived the household of an heir and the state of a citizen. The *Digest* and the Justinian code made abortion a criminal offense, but these prohibitions date from a later period and in the Roman Empire, as well as in the Hellenistic world, abortion seems to have been very common among the upper classes. The Christian church opposed the pagan attitude and in its canons abortion became a sin. As a result legal practises in Christian communities under the influence of the church made it a crime punishable with varying degrees of severity, although Anglo-Saxon law considered abortion an ecclesiastical offense only.

Among primitive peoples there are many various reasons for abortion. The same economic motives which are operative in the case of infanticide are operative also in the case of abortion. Psychological motives are also of considerable importance. A significant factor is a fear of disgrace because the child may be born out of wedlock, or because it may be born too soon after marriage, or because it may mean more than a certain fashionably approved number of children, or because the child may appear at the wrong time. No less effective are motives of vanity or the fear of losing the attention of the husband. Under primitive conditions when lactation is a prolonged process, the woman fears that the prescribed continence during that time is undesirable or unpleasant to the husband, and in order not to alienate his affection she will avoid giving birth to a child. Often the difficulties of a nomadic life will make women seek to avoid the additional burden of childbearing. Primitive women never resort to abortion for the protection of their own

health, although some may resort to it in order to escape the pains of childbirth. In India child marriage and frequent early widowhood force women to resort to abortion in order to hide illicit sexual relations. In Persia to give birth to a child means death to an unmarried girl, widow or divorced woman, and accordingly abortion is frequently resorted to. Among Moslems there is an additional reason in the credence given to a pregnant woman's superstitious fear that she may have a bad delivery. For this and other reasons it is claimed that in Moslem countries there are public places for the practise of abortion.

In communities living within the pale of western civilization abortion is also common although, because of the usual legal prohibitions and restrictions, information as to its frequency is difficult to obtain. The motives for the practise are much the same as in primitive communities, except for the one difference that the disgrace which is attached to the unmarried mother is greater among civilized than among primitive peoples. Available information, however, shows that abortion is more common among married than among unmarried women. The explanation of this fact may be found in the lenient attitude of the community toward the married woman as compared with the critical attitude toward the unmarried, making the former far less afraid than the latter to confess to abortive practises.

A survey made among the practising physicians in Maine showed an estimate of 63.5 percent of abortions as criminal; while a nationwide survey among one hundred physicians brought the estimate that one third of all pregnancies throughout the country end in abortion, giving an absolute figure of not less than 100,000. A large number of these are criminal, causing the death of some 6000 women yearly. In Great Britain, exclusive of Ireland and Scotland, "it is estimated that of legitimate pregnancies one in twenty end in stillbirth, and of illegitimate one in ten." Bertillon reported that the proportion in France was 193 to 1000, while Doleris claimed that between 35 and 40 percent of pregnancies in France were interrupted, and Landroy stated in 1912 that there were then more abortions than births, there being 70,000 abortions to 63,000 births in Paris. In France the abortions number 500,000 annually or nearly two thirds of the births. In Denmark the illegitimate stillbirths are twice as numerous as the legitimate. A study made of

criminal abortion in East Prussia indicates a frequency of between $\frac{1}{2}$ and 2 percent of all pregnancies. It is also estimated that in East Prussia from 70 to 80 percent of premature births at all stages of pregnancy are due to interference. Dutch statistics vary from 7 to 33 percent, according to the experience of the obstetrician. Russian statistics indicate about one third, and American experience is said to indicate the same number of purposely interrupted pregnancies.

The East Prussian study mentioned above gives as motives for the practise of abortion in one third of the cases the fact that a new child could not be maintained without lowering or impairing the standard of living of the family. In 25 percent of the cases the families believed they had all the children they could support; in another 25 percent the parents said that they did not wish to be inconvenienced by children; in 13 percent the mothers were unmarried and feared the disgrace attaching to their condition; in 4 percent the illness of the mother was the reason for abortion; and in the remainder of the cases the cause was the mother's fear that she would die during labor or that she would give birth to an unhealthy child. It appears, therefore, that except in cases in which the health of the mother demands it, the practise of abortion in civilized communities is primarily due to motives of material comfort in the case of married women and to the convention of chastity in the case of unmarried women. It is difficult to establish any connection between actual poverty and abortion in civilized society, whatever may be the case in primitive communities. Abortion is due in part to the general attitude of a community toward birth control or the limitation of offspring, and it will be resorted to when and where contraceptive methods are forbidden or not well understood.

Abortion will also be found to be a consequence of the urban middle class attitude toward illegitimacy. Although the dominance of the city has extended bourgeois morality over the whole social structure, it is still true that in communities living under peasant or semi-peasant conditions abortion is by no means general, although it is known and practised. In such communities children are generally considered a blessing and a child is not considered illegitimate when born before marriage, as long as the father is known and it is expected that marriage will soon follow. Nevertheless,

under the pressure of contact with urban conditions, this attitude is disappearing. Church influences are also helping in this direction. The tendency of young men to go to the city for work or for army service removes them from the influence of the local mores and marriage no longer follows the birth of an illegitimate child as a matter of course. In such a situation the mother is likely to resort to abortion because she is afraid of finding herself in disgrace. Moreover, if her parents do not approve of the suitor, the daughter may resort to abortion in order to avoid their wrath.

The urban mores of the middle class have enhanced the value of chastity, and the legitimation of pre-nuptial conception has become obsolete. Greater impersonality of social relationships, the desire for fewer children, the greater seclusion of women, the increased instability of the male, the possibility of sexual relations for the male in the city without recourse to matrimony or danger of offspring, the larger influence of religio-moral ideals and perhaps also a reaction away from rural customs are additional reasons. As deviations from the current moral code become more offensive, there is a greater necessity to hide such deviations and abortion is one of the means adopted.

As to the methods of abortion, Hovorka and Kronfeld classify them in three groups, as follows: first, mechanical, which includes indirect methods (lifting heavy weights, jumping, bleeding) and direct methods (perforation); second, internal medicine, which may be either purgatives or "special" remedies such as juniper; third, magic practises. They also enumerate 174 objects, instruments and methods found in use in classic and modern times and among primitive and civilized communities.

The general legal and moral attitude in most modern communities is in contrast to that of Soviet Russia. Under the czarist regime the penalties for the aborting mother and for the person who performed the abortion were extremely severe. The Soviet regime abolished these penalties in 1917 and made abortion legal. This new situation soon resulted in a crowding of the hospitals with women suffering from infections resulting from unscientific operations. The government decided to exercise supervision over the matter and in 1920 it became illegal for abortions to be performed outside of hospitals or by unqualified persons. In 1924 it was provided that petitions for abortion should be presented to a local commission composed of

one doctor and a number of members of the local women's organization. The women consider the social and economic conditions of the applicant and decide whether, in her economic condition, she has enough children; the doctor decides the matter from the standpoint of the effect on the mother of the forthcoming delivery. In a city of about 30,000 inhabitants the commission, sitting once a week, received applications from 20 percent of the pregnant women and granted permission to 18 percent. The legalizing of abortion is said to have resulted in no increase in the number of aborting women, as the proportion in Russia is the same as in Germany where abortions are still illegal.

The literature of the problem is shot through with discussions as to the moral justification for the practise. Havelock Ellis has given a full discussion of this aspect, which is essentially in contrast to the social-scientific analysis presented here. Much to the point are the remarks of Iwan Bloch that it is utterly inconsistent for the state to consider as sacred the life of the child before it is born and to punish anyone who interferes with its preservation, and then to consider that same child as a bastard as soon as it is born and for the rest of its life.

ABOUT, EDMOND (1828-85), French man of letters and popularizer of economic doctrines. He was educated at the Ecole Normale and at the French School in Athens, and devoted himself to literature and to political and

economic writing. As an economic writer he popularized the orthodox laissez-faire doctrine on labor problems, doing this first as a story teller in *Maître Pierre* (Paris 1858) and in the *Lettres d'un bon jeune homme* (Paris 1861), and then in a more direct and didactic manner in *Le progrès* (Paris 1864), *L'A B C du travailleur* (Paris 1868), and *Le capital pour tous* (Paris 1868). In his political writing he is known chiefly for his *La question romaine* (Paris 1859, tr. by H. C. Coape, London 1859), a bitter denunciation of the regime of the papal states and a plea for nationalism in religion. Though About was on friendly terms with the government of the empire, the book had to be published in Brussels and was forbidden admission into France. After the fall of Napoleon About accepted the republic and became the editor of the review, *Le 19^e siècle*, which he made an organ of anticlericalism and conservative republicanism. He also published an extremely nationalistic book on *Alsace* (Paris 1873). His work in literature won him membership in the French Academy (1884). A selection of his letters was published in *La nouvelle revue*, 3rd series, vol. xxi (1911) 289-322.

ABOVIAN, KHACHATOUR (1804 or 1805-48), also known as K̄hachatur Andonian Aboviantz, founder of modern Armenian literature and great pioneer in popularizing education. He was born in a small village near Erivan, the son of well-to-do and distinguished parents, and enjoyed the advantages of the best schooling of his time. In his early years he became intimately associated with several German scientists traveling in the Caucasus. In 1830 he studied at Yuriev (Dorpat) University on a fellowship. He returned to Tiflis six years later and became headmaster of a school; later he occupied a similar position at Erivan.

In 1839 he composed a primer for beginners to make teaching intelligible and learning attractive in the elementary grades. This was followed in 1841 by *Verk̄ Haiasdan̄i*, a novel written in a vividly descriptive style, interspersed with folk songs and portraying faithfully the political and economic conditions under which the common people lived and suffered. He also wrote fables in verse, poems, short plays

and essays, many of which served as reading texts in schools. His literary as well as his pedagogic work was done in the Armenian vernacular as distinguished from the "written language" of the time, which was ponderous and unintelligible to the masses. Abovian's activity served thus as a turning point in the method of Armenian education and opened the modern era in Armenian literature. His works, in Armenian, were collected and published by Isaac Zhamhariantz (Moscow 1897).

LEON ARDZROONI

Consult: Haxthausen, A. von, *Transkaukasien* (Leipzig 1856), tr. by J. E. Taylor (London 1854) p. 203-46.

ABRAHAMS, ISRAEL (1858-1925), Anglo-Jewish teacher, author and communal worker, was educated at Jews' College and at the University of London and from 1899 until 1905 acted as senior tutor at the former institution. He also was reader in Rabbinics at Cambridge University until his death. One of the founders of the Jewish Religious Union, later the Liberal Jewish Synagogue, he acted as lay preacher at frequent intervals. Together with Claude G. Montefiore he was the founder and joint editor of the *Jewish Quarterly Review* from 1888 until 1907 and in this capacity had a far reaching influence on the development of Jewish learning throughout the English speaking world. He was also one of the founders of the Jewish Historical Society of England, and until his death edited the society's *Transactions*.

Abrahams was a prolific writer and possessed the rare ability to popularize abstruse subjects. He published a considerable number of volumes of essays on various phases of Jewish history and literature. His best known book is his *Jewish Life in the Middle Ages* (London 1896), a pioneer work in the field of Jewish social history. Abrahams utilized the *Responsa* of the mediaeval rabbis for the history of that period and, after the works of Berliner and Gudemann, his was the first attempt to give a composite picture of Jewish life in all countries during the Middle Ages. His *Studies in Pharisaism and the Gospels* (Cambridge, Eng. 1917; 2nd series, Cambridge, Eng. 1924) marks a distinct step in advance in the treatment of the problem of the relations of the Gospels to rabbinic literature.

JULIUS H. GREENSTONE

Krass and C. G. Montefiore in *Jewish Studies in Memory of Israel Abrahams* (New York 1927) p. xi-lxvi.

ABSENT-VOTING. The expansion of business enterprises from purely local operations into statewide, interstate and even international activities during recent decades, the multiplication of itinerant vocations, the greatly augmented number of state and federal officials and employees, the enormous influx of students into colleges and universities, together with the ease and rapidity of modern means of transportation and intercommunication, have entailed the absence of thousands of eligible voters from their legal voting residences throughout much of the year, often including the days when primaries and general elections occur.

Until the enactment of absent-voting laws, beginning with Vermont (1896) and Kansas (1901, 1911), such voters were in effect disfranchised if unable to appear in person at the polls in their home precincts on primary and election days. To remedy this defect in our election system, all but three states (Connecticut, Indiana and Kentucky) now (1929) have laws which permit such absentees to mark an official ballot (a) at home, in anticipation of absence on election day, or (b) at some other place in the voter's home state, where he may happen to be on the day of election, or (c) at some point outside of his own state. The ballot thus marked is mailed, or delivered in person, either to the election officials in the voter's home precinct, there to be counted on election day, or to a county canvassing board or official, to be counted at the official canvass shortly after the election.

The earliest absent-voting laws were exclusively for the benefit of citizens serving in the Union army during the Civil War; and at least two such laws (in Maine and Pennsylvania) are still on the statute books. At the present time, however, only four states (Maryland, New Jersey, Pennsylvania and Rhode Island) restrict the privilege of voting *in absentia* to persons in the army or navy. While most of the mobile classes of the population are now taken care of, no state permits absent-voting, indiscriminately, by all classes of civilians. Most laws prescribe that the voter shall be "unavoidably" or "necessarily" absent, or absent "because of his duties or occupation." The law of Michigan is more specific and generous than most of such laws, extending the privilege of absent-voting to persons in the actual service of the United

States or of the state, students in institutions of learning, public-school teachers, persons enrolled in military or naval training camps, members of the legislature while attending legislative sessions, railway employees, commercial travelers, sailors engaged or employed on the Great Lakes or in the coastwise trade, and "persons necessarily absent while engaged in the pursuit of lawful business or recreation." Although absence from the election district is a usual prerequisite, about fourteen states, including Michigan, allow absent-voting by persons detained at their homes by illness or disability.

The meager statistics available indicate that comparatively few voters actually take advantage of the absent-voting laws. The explanation is largely to be found in the newness of most of these laws and the failure of election officials and party workers to give adequate publicity to the opportunities which they hold out.

Absent-voting legislation has been held unconstitutional by the state supreme courts in Kentucky (1921) and, as it applies to the civilian population, in Pennsylvania (1925).

ABSENTEE OWNERSHIP. Separation of the place of residence of property owners from the location of the property from which they derive an income and which they ultimately control gives rise to economic and social problems of wide ramifications. The subject seems first to have attracted serious attention in connection with conditions in pre-revolutionary France. Here one of the important factors in the situation was the removal of the higher nobility to the capital after the final triumph of the crown over feudalism in the mid-seventeenth century, and their transformation into elegant, but parasitic and extravagant courtiers. It must be observed that clear recognition of absenteeism as an active cause of the discontent which culminated in the revolution is much easier to find in the analyses of later historians than in the writings of the period, though antipathy to the

bailiffs who managed the estates is one of the recurring notes in the *cahiers* of 1789.

Historically absenteeism is more famous, or at least has received much more discussion at the hands of recognized economists, in connection with the Irish question, which was so important during the nineteenth century. More recently a similar agitation has been carried on in regard to India. Around the middle of the century it was estimated that as much as one third of the entire produce of Ireland was sent out of the country in payment of rents to absentee proprietors. The leading economists of the liberal school took an active interest in the Irish question, and the effects of absenteeism were argued especially by McCulloch, Longfield and Senior. McCulloch held that it is a matter of indifference whether proprietors live and consume their incomes in the country or abroad. Longfield, lecturing at Dublin in 1834, admitted the validity of much of the orthodox liberal reasoning, particularly as against popular arguments, such as that of Swift, to the effect that the country was being drained of its gold and silver. But he endeavored to show that absenteeism is disadvantageous in various ways. Senior took a somewhat intermediate position, but nearer to the indifference side. Longfield's reasoning as to effects on prices and costs raises issues of general theory not yet settled, but he showed a good deal of insight in emphasizing social considerations. He particularly stressed the influence on the quality of agricultural management due to the interest a resident will naturally take in his estate, and also the influence of the proprietor's leadership and example in community affairs and mode of life. He held it to be axiomatic that any influence exerted would be for the good, since any bad example or suggestions would be ignored. It is of interest that Adam Smith inclined to the opposite view, that the residence of wealthy spenders in a community tends to corrupt rather than to improve social morale.

In the past two generations the question of farm tenantry has received extensive notice in the United States, as the general problem of land tenure has always and everywhere. But factual study shows that conditions in America do not involve on a considerable scale the holding of land for investment by absentees. In this country absenteeism is more discussed in connection with "industry" and, in particular, the separation of investment from control through various modern devices of corporate

organization and finance, holding companies, classification of securities, banker domination, etc. The high point of the attack on grounds of general social effects is perhaps Thorstein Veblen's *Absentee Ownership*. Currently the discussion of branch banking and chain stores exemplifies argument or prejudice in one direction, opposite to that shown in the general scramble of communities to secure immigration of capital or its owners on nearly any terms.

Allusion has already been made to some of the theoretical issues raised by the general question of absenteeism. Such ideas as that of draining a community of its money may of course be dismissed. In the logic of abstract individualistic economics, it is a matter of indifference to all other individuals where any particular individual resides. Even the matter of men's pleasure or displeasure in each other's society would theoretically find effective expression in the competitive determination of places of residence (though only to the extent that such feelings are mutual). In this field, as in others, the classical economists reasoned awkwardly and often erroneously to conclusions which have a sound theoretical basis, which actually represent the main long-run economic tendency, and which are generally correct in their practical emphasis as against ruling popular fallacies. But, in the first place, some of the implicit assumptions of the individualistic theory are more or less contrary to fact and reasonable possibility and, in the second place, there are questions of community interest which are not practically reducible to individualistic terms.

Relative to the first head are some consequences of mobility and immobility. Any measure which increases the population and volume of business in a community naturally works to the direct economic advantage of the owners of immovable wealth in that community, and more or less to the advantage of the numerous other sorts of persons who have localized vested interests. Some productive activities (some "industries") are located, either by necessity or because of decisive advantage, near immovable natural resources or other productive conditions; some follow the residence of the consumers—this is true strictly of personal services and in varying degree of final manufactures; some can without great difference in technical efficiency be moved about inside wide limits. Consequently the issues involved in absentee ownership overlap exten-

sively with those involved in the broader questions of interregional economic relations, specifically, "protectionism" in all its forms. There is no doubt that Senior followed a sound intuition in making the effect of absenteeism depend to a considerable degree on whether conditions in the "home" country are such that the income would be transferred in the form of raw produce or in that of manufactured goods.

Of community interests which do not find adequate expression in contracts between individuals the most immediate and direct is the political, including taxation and military service. Neither of these goes absolutely with location, but in general that connection holds. Distribution of power to tax and of the proceeds of taxation between the community which is the source of the wealth and that in which the owner lives was one of the early questions taken up by the League of Nations, and is a source of growing conflicts of interest within all large nations; it holds possibilities of an especially acute sort for a federal system such as that of the United States, and in general confronts with a theoretically insoluble problem all efforts to combine local autonomy in government with political unity on a broad basis.

Less tangible but equally important consequences of place of residence are expressed, in their extreme development, in the whole difference between a rural and an urban civilization. Even in modern industrial nations cities are predominantly aggregations of consumers, and of the service occupations and industries which supply the immediate wants of consumers. And since in a broad sense civilization is an urban phenomenon it is also a phenomenon of absenteeism in its manifold variations. The political effects obviously depend on the extent of the separation of political jurisdiction between the localities of residence of owners and of the property itself.

A phase of absenteeism which has received much attention first and last is the effect on labor policy. It is undoubtedly true that a humane attitude on the part of employers, in opposition to their purely economic interest, is more likely to go with some personal contact—though the reverse may hold in some cases. More important, undoubtedly, is the greater likelihood of an *intelligent* policy of control, working to the mutual economic advantage of employer and employee, when there is direct contact without the intervention of a managerial bureaucracy. But again, a salaried adminis-

trative staff may be more, and not less, intelligent in personnel policy in comparison with ultimate proprietors. It is difficult to generalize, and if independence and self-reliance are recognized as ethical values and paternalism as a danger, it is clear that "there are two sides" to the whole question of personal relations versus the cash nexus.

ABSENTEE TAXATION. *See* TAXATION.

ABSENTEEISM (LABOR) refers to time lost in industrial establishments by avoidable or unavoidable absence of employees. Time lost by strikes and lockouts or by lateness amounting to an hour or two is not usually included. Absenteeism is measured either in the percentage of time lost as compared with the total scheduled time of work including authorized overtime, or more popularly in the number and fraction of working days lost per year. Since working days approximate three hundred per year, the percentage of time lost may be translated into days lost per year by multiplying by three.

A further and more important complication in measuring absenteeism lies in the lack of any standard upper limit to the period of absence. When an employee has been absent, say nine months, some establishments may continue to keep his name on the books and to add in his lost time, while other establishments may consider that he has left his employment and will simply "write him off" as a case of

labor turnover. The lack of any definite limits where absence passes into labor turnover restricts the use of statistics of absenteeism in the comparison of different establishments, different industries or different countries.

If a limit of six months is taken arbitrarily, then the "unavoidable" loss of time due to sickness and non-industrial accidents may be estimated for England and America as averaging about 1.85 percent for men and 2.20 percent for women or about five and a half working days per year for men, six and a half for women (Florence, p. 202). This rate varies seasonally, sickness being considerably higher in winter than in summer. The other elements in unavoidable absenteeism are more difficult to average. Absence due to industrial accident varies greatly from industry to industry. In the metal industries of both America and England the time lost by men on account of industrial accidents is about one and a half days per year. Probably the accident rate is roughly the same on railways but two or three times as much in coal mines and less than half in textiles and other manufacturing industries. Adding all elements in unavoidable absenteeism, male employees may be expected to lose from six to ten and a half working days per year, i.e. 2 percent to 3.5 percent of their time, according to the industry, in unavoidable absence of not more than six months' duration.

"Avoidable" absence, that is, absence not due to sickness, accident or family circumstances, is yet more variable, and the *total* absence found by actual record during the period of the war in various English establishments ran from 5.3 percent to 14.3 percent of the total working time in the case of men and from 7.6 percent to 12.3 percent in the case of women (Florence, p. 189). In post-war days the Royal Commission on the Coal Industry reported 22 $\frac{3}{4}$ days lost by coal miners in 1924 due to all personal causes, i.e. almost 8 percent of the total working time, but the proportion varied widely from district to district, and in the intensive investigation of the Industrial Fatigue Research Board absenteeism in a group of ten collieries was found to average 12.5 percent.

The chief source of absence statistics in America are not government inquiries but the records of individual establishments. Establishments keeping and publishing such records would naturally be the more efficient, and hence it is not surprising to find a lower total absence rate centering around 5 percent of scheduled

time, with percentages still lower among office staffs and in "model" establishments as a whole. Where government inquiries were made, however, such as in southern cotton mills and in shipyards during the war, rates of 11, 13 and 18 percent are quite comparable to the British extremes (Douglas). But in the Far East such statistics as have been published show a wide divergence from rates in the western countries, indicating an altogether different type of economy. The proportion of absence in Japanese coal mines runs as high as 33 percent for men and 45 percent for women.

Absenteeism is a serious problem in factory management because it involves heavy additional expenses. Either reserves and understudies must be held in readiness to take the place of the absent, or the overhead cost of idle equipment must be faced. Industrial employees do not usually ask leave to be absent beforehand or even give notice during an absence as to its expected length, so that the management is generally left in uncertainty as to the probable duration of any employee's absence and cannot take appropriate measures to fill the gap. The first obvious remedy which a wise personnel management should adopt to reduce the heavy expenses of absenteeism is therefore to encourage notification, especially in cases such as sickness when the duration of absence is likely to be long; and where other personal and family circumstances, e.g. illness of children in the case of married women employees, make absence unavoidable, to grant leave of absence liberally. A second type of remedy open to the factory management is to reduce the unavoidable absence due to sickness and industrial accident by recourse to the programs of the industrial hygiene and safety movements.

The wide margin between total and unavoidable absenteeism points to a third line of attack, namely the reduction of avoidable absenteeism. To some extent regularity of attendance may be encouraged by bonuses and other pecuniary inducements; but more can be effected by removing the underlying causes of absence. Absenteeism is probably a natural human reaction to the routine of the modern factory. There is a maladjustment between man's instincts and desires and the regular working habits that are imposed upon him. This routine can be relaxed or modified by granting vacations with pay, shortening or redistributing scheduled hours, having employees live nearer their work, and adjusting the physical conditions of the plant,

especially noise and ventilation. There is probably considerable physiological and psychic fatigue not sufficient to make a person recognizably ill, yet reducing the feeling of fitness and inducing an aversion to work. Minor and often avoidable physiological complaints appear to be a fertile source of the markedly higher rates of absenteeism found among women members of office staffs.

ABSOLUTISM in the history of political theory has stood for two doctrines: the absolutism of the seventeenth and eighteenth centuries and Hegelian absolutism. These doctrines, separated in time and appearing at first sight to differ in substance, have yet, as we shall see, a definite historical connection. Absolutism in the seventeenth and eighteenth centuries was a doctrine suited to the absolutist monarchies which had been gradually coming into being since the Reformation. As a theory (e.g. in Hobbes) it applies to all governments—oligarchies and democracies as well as monarchies—but in practise its protagonists are always thinking of monarchies. It is the doctrine of the absolute right of the ruler, i.e. the affirmation that the ruler is bound neither by the laws of nature nor by any kind of moral or legal limitation. It is connected obviously with the doctrine of sovereignty which, first formulated with

limitations by Bodin in the sixteenth century and given its classical definition by Hobbes in the seventeenth, was, as Jellinek says, a negative protest against the limitations imposed upon the growing nation states by the empire, the church and the feudal rights of the nobility. The nation states of Europe, as they were consolidated in the sixteenth and seventeenth centuries, were absolutist in the sense that they were released from these limitations. The ideal of a unified political organization for Christendom was finally abandoned and the absolute independence of the several sovereign states was recognized; the secularity of the state, its independence of, or superiority to, the church, and the omniscience of the central government over old standing customs, privileges and private jurisdictions were the more outstanding features of this new type of state.

But the distinguishing characteristic of the new state and the essence of absolutism is the state's relation to law. The mediaeval state rested on law. The monarch was above positive law but subject to the law of nature. This law of nature was conceived of as something fundamental and unalterable even by God, on the acceptance of which all society depended. Most sixteenth century writers, however much they may assert that the power of government is free from the more external limits, take for granted the overriding compulsion of the law of nature. It was Machiavelli's repudiation of such compulsion that made him so revolutionary a figure. But when the new movement comes to its maturity in Hobbes, the laws of nature are reduced to mere rules of expediency—with the far reaching consequence that for the view that social relations, and with them the state, are founded on law, is substituted the view that law is thought to be dependent on the state. These rules, says Hobbes of the laws of nature, men used improperly to call laws. For law is the word of him who by right exercises command over others. It is thus regarded as a command and as nothing else: its authority comes not from its content but from the authority of the person who commands it. This new attitude, as Figgis has pointed out, has its counterpart in contemporary theology. To Calvinist and Jesuit alike, actions are right because God commanded them—they are not commanded by God because they are right.

From this new conception of law all absolutism follows. If for the existence of law an *a priori* relation of commanding and obeying is

necessary, then personal authority is the basis of the state. To such authority there can be no limitations: for the only possible limitations would be another commander, which would mean anarchy; or the universal acceptance of some principle that should either delimit the spheres of different authorities or limit the commands of the one sovereign, which would mean that the law was not a command.

The basis for that personal authority may be expediency, as in Hobbes, or religion, as in the theory of the divine right of kings. The inner compulsion of absolutism is always the same. Man cannot be trusted to recognize and interpret any general moral or social principles; and that being so the only way in which the agreement and conformity necessary to government may be attained is the recognition by all of the authority of some person or persons who shall have entire power to do all that is necessary for society. There is paradoxically a connection between absolutism and toleration, as is clear from Hobbes. Agreement to obey an arbiter is the refuge of those who cannot agree on moral principles to guide their conduct.

Hobbes' absolutism was supposed to be compatible with other forms of government than monarchy. Government might be of one or more persons: its powers must be absolute in all cases. The monarchical absolutism of the divine right of kings was succeeded by the democratic absolutism of Rousseau, who marks the transition from the first kind of absolutism to the second. Rousseau takes for granted that law is a command but he also assumes that no individual has a right to command others. He therefore looks for an entity with the necessary authority to command, whose authority is to be compatible with the freedom of the individual citizens, and he finds what he seeks in the community or the general will. The omniscience and unlimited powers of the monarch are now transferred to the general will. This democratic absolutism upholds the complete independence of the nation state and the complete authority of this state over all other associations. Nevertheless it has to make a distinction between the actual government and the general will. Rousseau's doctrine is thus a return to the notion of government being limited by law, although his assumption that law is a command obscures the fact of this return. Rousseau's general will is really not a person who issues commands but a principle.

Rousseau's doctrine of the sovereignty of the

general will was restated by Bernard Bosanquet in his *Philosophical Theory of the State*. Absolutism for Bosanquet, as for Bradley and other English Hegelians, has primarily a metaphysical meaning. Kant had shown that it is the nature of reason to seek for the unconditioned. For the Hegelians who made reason constitutive and not, as Kant insisted it should be, merely regulative, this meant that truth was to be found only in the unconditioned or absolute. Hence the distinction between appearance and reality based on the principle that what is in any way conditioned is so far only appearance. When this general point of view is applied by Bosanquet to political theory it easily takes up the suggestion from Rousseau that the sovereignty of the state can only reside in the community as a whole and that against the claims of such sovereignty there can be no limitations. The view that law is a command with its consequent denial that sovereignty can be in any way limited is retained by the conception of the state as a personality.

This modern absolutism involves a confusion between the state and society, and tends to ascribe power to political government over other associations, as for instance the church, on the ground that the state is society as a whole. It has been much criticized by recent political theorists, particularly Hobhouse, Laski and MacIver, on that score. It certainly does not do justice, moreover, either to international cooperation or to the original claim upon the loyalty of the individual made by such an institution as the church. The omniscient, entirely independent state which absolutism in all its forms presupposes no longer exists. It may perhaps be said that the modern state is returning more and more to a conception of political society more akin to the mediaeval than to that of which absolutism is the expression. It insists on the reality of the notion of a world society; it thinks of power as always conditioned by law or agreed principle; it is federalist rather than unitary; and it is no longer satisfied with the conception of law as a command. With all these positions absolutism in any sense is incompatible.

ABSTENTION FROM VOTING. *See* NON-VOTING; OBSTRUCTION, PARLIAMENTARY.

ABSTINENCE is the term employed by Senior and, following him, by later economists of the English classical tradition to designate the peculiar element in the cost of commodities which is involved in the use of capital in production. Since to the older economists cost meant sacrifice or pain, abstinence may be defined as the productive sacrifice for which the distributive share of interest (in the older usage, profit) is the remuneration. There were more or less definite anticipations of Senior's doctrine by earlier writers, especially by Scrope, who used the term in 1833, and perhaps by G. Garnier (*Abrégé élémentaire des principes de l'économie politique*, Paris 1796).

Lassalle and others have effectively ridiculed the abstinence pain of the wealthy capitalist as a justification for the payment of interest; but this has no bearing on the notion of an equivalence between reward and sacrifice, at the margin, for each individual saver, as a causal explanation. The English economists, prior to the rise of the Austrian school, did not use the abstinence theory to develop a quantitative explanation of the rate of interest—a fact connected with the generally undeveloped state of their distribution theory in comparison with the theory of value. According to Senior, abstinence sets a minimum level of "profit," but this, like his maximum, is quite indeterminate, and the notion that some interest is a necessary inducement to saving was accepted doctrine before he wrote (*cf.* especially James Mill, but also Smith, Ricardo *et al.*). Ricardo, moreover, has recognized that the value of commodities is affected positively by the length of time expended in production, independently of other causes. Jevons, the English pioneer in deriving value from utility in place of cost, discussed the psychology of present and future satisfactions

in connection with the theory of utility; but though he ostensibly reconciles his theory of capital with the abstinence concept, the theory actually runs in terms of the productivity of investment (*Theory of Political Economy*, 4th ed., London 1911, p. 71 *et seq.* as contrasted with p. 233 and p. 247).

The modern discussion of capital and interest dates from the publication of Böhm-Bawerk's first (historical) volume in 1884. This writer gave an elaborate development of the theory of preference of present to future goods and made one of three main grounds for this preference the "technical superiority" of the former, due to the greater effectiveness of roundabout processes in production. Since that time discussion has been centered on the two main issues: first, whether this technical superiority of present goods is different in principle from the productivity of capital rightly interpreted; and second, whether the view of a non-technical, psychological preference is different in principle from the doctrine of abstinence. Regarding the latter distinction Böhm-Bawerk defended to the last his ingenious contention of 1884 that abstinence cannot be treated as a sacrifice additional to the labor of producing a capital good, and that the discount of futurity is a separate, in fact contradictory, principle. Of the two leading American advocates of a psychological in opposition to a technological explanation of interest, Professor Fisher has supported Böhm-Bawerk, while Professor Fetter adopts and uses the abstinence notion without protest. The majority of economists, however, seem to agree with Alfred Marshall that the distinction is fallacious, a matter of words or of psychological subtlety. Commonly, however, they prefer the term "waiting" to "abstinence," a substitution first suggested by Macvane in 1887. The view is that this waiting, abstinence, or discount of future enjoyment, is the chief factor limiting saving and hence determining the supply curve for capital.

Aside from the question of the relations between technological and psychological factors in the capital and interest situation, the psychological theory itself is admittedly in an unsatisfactory state. J. B. Clark and others have suggested that a low rate of interest might stimulate more saving than a high rate. Cassel holds that the facts involve a connection between the interest rate and the length of human life. Inasmuch as at the ordinary rate

of interest it is doubtful whether on the average invested savings replace themselves with an increase during the lifetime of the saver, and in view, further, of the large proportion of the income from capital which is constantly reinvested, it is arguable that the term abstinence is after all more descriptive than waiting. And the same reasoning casts doubt over the realism of the whole view of the psychology of saving as a comparison between present and future enjoyment. In this field of economic behavior an institutional interpretation seems especially applicable.

Even from the standpoint of rationalistic economics the abstinence-time-preference theory needs to be carefully stated. In a world where opportunities are notoriously open to all to secure through technical investment larger quantities of goods in the future in exchange for a present sacrifice, the rational individual must carry saving to a point at which there is a psychical cost equal to the gain. But this does not make abstinence or time preference the cause of the gain. It seems dangerously near to "idle speculation" to theorize in general terms as to what behavior would be in the absence of this fact, or to say what behavior is to be regarded as rational in the face of all the unknown quantities which affect future needs and future resources. Moreover the bulk of the capital supply actually comes from "postponement" of consumption until after death. It is surely inaccurate to describe as a preference of present to future enjoyment (or a sacrifice incurred in postponement) the fact that men will not voluntarily postpone all consumption to the indefinite future. The only workable zero-point for reckoning time preference is that of a uniform rate of consumption through the individual life, or the responsible or "normal" part of it, and on this basis the view that civilized man typically looks ahead excessively and "borrows trouble" is abstractly as arguable as the reverse contention. It is to be observed that even a rate of consumption is not a magnitude susceptible of objective measurement.

It is fairly safe to say that the most fruitful approach to the problems affected by abstinence or related conceptions is a realistic analysis of the conditions of supply and demand for consumable goods, for the instrumental or indirect goods behind these, and ultimately for "capital" and "loanable funds." Although there is now much disagreement among competent economists regarding ultimates, the drift seems to be

toward a view which gives a relatively minor place to the psychological comparison of present and future enjoyments as an element in the situation at a given moment. For it is to be noted, finally, that beyond question industry could absorb vast amounts of capital at a low interest rate (elastic demand), while no possible change in conditions affecting saving can in a short time make a large difference in the aggregate supply of productive capital.

ABUL FAZL ALLAMI (1551-1602) was the son of the Shaikh Mubārak, who first suggested to Akbar, the Mogul emperor, that he should become the spiritual head of his empire. The emperor, after coquetting with Hinduism, Jainism, Zoroastrianism and Christianity, finally in 1552 established as the official religion the Dīn Ilāhī, or Divine Faith, a kind of theosophy of which Abul Fazl was the high priest. This excited the rage of orthodox Moslems, and in 1602 he was brutally murdered at the instigation of Prince Selīm. Abul Fazl was one of the emperor's most intimate friends, "the King's Jonathan," say the Jesuits, and for his encyclopaedic learning and courtly attainments he has been compared to Francis Bacon.

Of his two great works, the *Akbar Nāma* (Reign of Akbar) (3 vols. Calcutta 1877-86; tr. by H. Beveridge as *Akbar Nāma*, pts. i-xiii, Calcutta 1907-21) is spoiled by its tendency toward fulsome panegyrics; the monumental *Ain-i Akbari* (Institutes of Akbar) (2 vols. Calcutta 1872-77; admirably translated by Biochmann and Jarrett as *Ain-i Akbari*, 3 vols. Calcutta 1873-94) is, on the other hand, really a gazetteer of Hindustan, and is one of the most

amazing things of its kind in the world. Its compilation occupied over seven years. Books I and III describe in detail Akbar's court and administrative system, with a statistical account of the empire. Nothing is omitted; prices, wages, coinage, architecture, manufactures, are carefully tabulated. Book II contains an admirable chapter on regulations for education, laying down for Indian schools an elaborate curriculum which includes mathematics, logic, agriculture, political science, history and theology. Books IV and V are devoted to a minute and learned account of the religion, philosophy and customs of the Hindus, and a collection of "Happy Sayings" of Akbar, of unique value for the light which they throw upon the emperor's character and views. This book has been criticized for showing Akbar's empire in too favorable a light, but even allowing for this, it is a work of the greatest importance for the study of the social and economic history of India in the sixteenth century.

ACADEMIC FREEDOM is the freedom of the teacher or research worker in higher institutions of learning to investigate and discuss the problems of his science and to express his conclusions, whether through publication or in the instruction of students, without interference from political or ecclesiastical authority, or from the administrative officials of the institution in which he is employed, unless his methods are found by qualified bodies of his own profession to be clearly incompetent or contrary to professional ethics.

The freedom of opinion, speech and publication claimed for the university teacher is not in extent significantly different from that usually accorded to other citizens in modern liberal states, and the reasons for maintaining it are in part the same. It is peculiar chiefly in that the teacher is in his economic status a salaried employee, and that the freedom claimed for him implies a denial of the right of those who provide or administer the funds from which he is paid, to control the content of his teaching. The principle of academic freedom is thus, from the purely economic point of view, a paradoxical one; it asserts that those who buy a certain service may not (in the most important particular) prescribe the nature of the service to be rendered. The reason why such freedom

is nevertheless socially necessary lies in the fact that there are certain professional functions generally recognized to be indispensable in the life of a civilized community which cannot be performed if the specific manner of their performance is dictated by those who pay for them, and that the profession of the scholar and teacher in higher institutions of learning is one of these.

There are three aspects of the social role of the scholar which make such freedom essential. In the first place, he is the technical expert, given a prolonged training and often a costly equipment, and set apart to investigate problems which it is not practicable for all men to investigate thoroughly and at first hand for themselves. His function is thus in part that of expert adviser or informant of the community at large on the questions which fall within his science. Secondly, his office has for the same reason some analogy to that of the judge. His opinions must be not only competent but disinterested. No one indeed is constrained to accept them; but if specialized knowledge and methodical inquiry by trained minds are to have in the long run the part in the shaping of general opinion and social policy which it is desirable that they should have, it is important that those who are appointed to this function should be free from intimidation and subordination. They should, moreover, be beyond reasonable suspicion of subjection to such influences, especially from economic groups. The third reason is the most important. The university is not only a vehicle for transmitting to successive generations knowledge already gained; it is, more distinctively, the chief organized agency for the advancement of science and the canvassing of new ideas. It is the outpost of the intellectual life of a civilized society, the institution set up on the frontier of human knowledge to widen the dominion of man's mind. The performance of this function of seeking new truths will sometimes mean, as it has repeatedly meant since the beginnings of modern science, the undermining of widely or generally accepted beliefs. It is rendered impossible if the work of the investigator is shackled by the requirement that his conclusions shall never seriously deviate either from generally accepted beliefs or from those accepted by the persons, private or official, through whom society provides the means for the maintenance of universities. Others still remain free to adopt or reject, to apply or disregard, new discoveries

or hypotheses, but the university's most characteristic task is to seek for them, cautiously and critically, yet without external restraints.

Academic freedom is, then, a prerequisite condition to the proper prosecution, in an organized and adequately endowed manner, of scientific inquiry and the communication of the results of it to the public and to students in the higher stages of their initiation into the intellectual life of their age. In the needs and rights of such students a further reason for maintaining the teacher's freedom is apparent. They are entitled to learn the contemporary situation in each science, the range and diversity of opinion among specialists in it; it is not the pedagogic province of the university to acquaint students merely with facts of common knowledge and with opinions accepted by the general public or the donors of endowments. The same rights of the student, however, demand of the university teacher, in his function of instruction as distinct from investigation and publication, special care to avoid the exclusive or one-sided presentation of his personal views on questions upon which there is no agreement among experts. He is not entitled to take advantage of his position to impose his beliefs dogmatically upon his students; the nature of his office requires that alternative opinions be fairly expounded, and that the student be encouraged and trained to reach his own conclusions on such questions through critical reflection upon carefully ascertained facts.

It has been held by some writers that in state institutions freedom of teaching conflicts in certain cases with another and more fundamental right—that underlying the principle of the religious neutrality of the state. Upon this principle the opponents of state religious establishments have usually based their case. But it has been argued that "if it is wrong to compel people to support a creed in which they disbelieve, it is also wrong to compel them to support teaching which impugns the creed in which they do believe." And if the teacher in institutions maintained by taxation is free to "teach" the theories he himself accepts, he may, and usually does, impugn the creed of some body of taxpayers, and sometimes of the majority of them. This argument has usually been employed by those who have attempted, in a number of American states, to obtain legislation prohibiting the "teaching of evolution" in state schools and universities—attempts which have been successful in Tennessee (1925), in Missis-

sippi (1927) and (through popular referendum) in Arkansas (1928). The hypothesis of evolution, it is contended, is in conflict with the belief of citizens who accept literally the Biblical narrative of the creation; hence the rights of the taxpayer are violated if instructors paid out of public funds are permitted to teach that hypothesis.

This argument, especially in its application to universities, is subject to two criticisms. First, it involves an ambiguous use of the word "teach." To "teach a theory" might mean merely to expound it; or to expound it and also to state the arguments of its adherents; or to do both of these and also to indicate the prevailing opinion of experts with regard to it; or to let the teacher's own opinion concerning it be known; or to inculcate it dogmatically or to proselytize in behalf of it. If laws prohibiting the "teaching" of certain theories in state institutions are construed only in the last, i.e. in the strictest, sense they do not essentially conflict with the principle of freedom of teaching as above set forth. They would leave entire liberty of inquiry, discussion and undogmatic expression of personal opinion to both teacher and student. The principal objection to them when they are so interpreted is that it is difficult or impossible to define so precisely and comprehensively, in terms of concrete acts, what would constitute violations of them as to bring the matter effectively within the scope of the criminal law.

If, however, prohibition of the "teaching" of any scientific theory not accepted by all taxpayers is construed in any other sense, it is incompatible with the maintenance by the state of institutions performing the characteristic functions of universities. It is evident that the principle of state neutrality cannot consistently be limited to a single hypothesis, but must apply to any "teaching" which any taxpayers believe to conflict with their religious or ethical convictions. A state may, in short, have a university or do without. But it cannot have one, in the usual and proper sense, if it excludes, under a misconception of the principle of neutrality, both a large part of the subject matter of science and also the method of free inquiry and free expression, which is necessary to the functioning of this type of social institution.

There exist in most communities private institutions of learning which do not fully accept the principle of academic freedom, and therefore do not undertake to perform the functions

mentioned. The legitimacy of their existence is generally admitted, but it is evident that a community in which only institutions of this type exist lacks adequate provision for the advancement of science and for the maintenance of that really fruitful "neutrality" in higher education which depends upon liberty of unbiased investigation and thought. Even in institutions of the restricted kind, however, it is commonly recognized that the limitations imposed should be formulated with reasonable definiteness in the charter or statutes, so that teachers may know, before accepting employment, to what requirements they are bound, and that the restrictions upon their liberty of opinion and teaching may not be subject to arbitrary and varying interpretation by administrative officers.

In some cases teachers have been dismissed or otherwise penalized because of their exercise, outside the university, of their ordinary political or personal freedom in a manner or for purposes objectionable to the governing authorities of their institutions. While such administrative action is contrary in spirit to academic freedom, it is primarily a special case of the abuse of the economic relation of employer and employee for the denial of ordinary civil liberties.

There are several principal means, aside from an enlightened public opinion, for the effectual maintenance of academic freedom. It is evident that the governing boards of universities or similar corporations should decline all endowments for the inculcation of opinions specified by the donor. The general control of admission to the teaching office should be in the hands of members of the scholar's profession, and primarily in those of specialists in the subject to be taught. The recommendations, with respect to appointments, of bodies representative of university faculties should not be rejected by state officials or lay governing boards unless there is evidence of corruption, favoritism or the acceptance of discredibly low standards of professional competence in the action of those bodies. But the chief practical requisite for academic freedom consists in guaranteed security of tenure in professorial positions, unless removal for some grave cause (such as proved incompetence or moral delinquency), other than the content of the teaching of the professor concerned, becomes necessary. Experience has shown that such cause may sometimes be officially alleged for dismissals which

are in fact due to pressure from economic, sectarian or other groups desirous of restricting freedom of teaching in some particular. Removal from professorial office should therefore be possible only through some definite form of judicial procedure in which the faculty, as the local representatives of the academic profession, should responsibly participate. The American Association of University Professors, which has contributed much to the formulation of a professional code for university teachers in the United States, has adopted the principle that "every university or college teacher should be entitled, before dismissal or demotion, to have the charges against him stated in writing in specific terms and to have a fair trial on these charges before a special or permanent judicial committee of the faculty senate or council, or by the faculty at large. At such trial the teacher accused should have full opportunity to present evidence" (*General Report on Academic Freedom*, 1915, in *Bulletin of the Association*, vol. i). This rule, however, does not apply to teachers on definitely limited or probationary appointment. But since the withholding of reappointment may also involve a covert or open denial of the teacher's freedom of thought or utterance, the question should, according to the declarations of the same association, always be passed upon by a competent faculty body.

The principle of academic freedom could not influence the policy and organization of universities until its two presuppositions had been formulated and become familiar: first, that science is not static nor even merely cumulative, but is a continual quest of new knowledge, to which old conceptions must be constantly readjusted; and second, that truth is more likely to emerge through the interplay and conflict of ideas resulting from the exercise of individual reason than through the imposition of uniform and standardized opinions by authority. These two ideas in conjunction first became conspicuous in modern thought in the seventeenth century. The new conception of a university as a place devoted to the continuous "advancement of learning" through an organized and cooperative "inquisition of nature" was vigorously enunciated by Bacon ("Prometheus" in *De sapientia veterum*, 1609, and *New Atlantis*, 1627); and both presuppositions found their most eloquent expression in Milton's *Areopagitica* (1644): "If the waters of truth flow not in a continual progression, they sicken into a muddy pool of conformity and tradition"; and "though

all the winds of doctrine were let loose to play upon the earth, so Truth be in the field, we do injuriously by licensing and prohibiting to mis-doubt her strength."

Yet in England these principles remained without actual application to universities for nearly two centuries. It was in Germany that academic freedom had its birth. In 1673 Spinoza was called by the elector palatine, Karl Ludwig, to a professorship in the University of Heidelberg, with the assurance that he would be given *philosophandi libertatem amplissimam*—though upon the understanding that this freedom would not be "abused to disturb the religion publicly established." Spinoza declined the call, partly on the ground that it was not clear how much was implied by the proviso. The principle of freedom of teaching was further extended in the subsequent new foundations in Germany, notably in the universities of Halle (1694), Göttingen (1734) and of Berlin (1809). The principle that "science and the teaching of it are free" became an article of the organic law of Prussia in the constitution of 1850.

The first non-sectarian university in England, the University of London (afterwards London University College), was opened in 1828. Not until 1854-56 were creedal requirements for the taking of degrees (other than in divinity) abolished in the older English universities. In 1871 the University Tests Act abolished all theological tests (with the same exception) for the holding of professorships, fellowships, scholarships and other emoluments in these universities and their colleges.

The early American colleges, founded by religious bodies, were subject in varying degrees to sectarian restrictions. These limitations, in force until the nineteenth century, were eventually abolished in all the more important of the older institutions. The earliest state university, established in Virginia in 1819 upon the plans of Jefferson, was non-sectarian, but there was no express enunciation of the principle of academic freedom in the act creating it; and the first appointee to its faculty, Thomas Cooper, though chosen by Jefferson himself, was removed under pressure from certain religious leaders. In later times interference with freedom of teaching in the United States has usually taken the same form: it has consisted in attempts by sectarian, political, economic or other groups to impose limitations not prescribed by statute or by the charters of the institutions concerned, usually through the dis-

missal of teachers whose opinions or utterances were obnoxious to these groups.

The above mentioned formulation by American university teachers of a code for the preservation of academic freedom indicates not only a growing professional cohesiveness but an increasing general awareness of the problem. Overt attempts at the control of teaching have probably become less frequent and, when made, less effective in recent years. The great and expanding cost of maintenance of a modern university has made private institutions—which are especially numerous and important in America—dependent upon a steady flow of large gifts from persons of wealth; and this situation, it has often been asserted, causes the teaching of the social sciences in such institutions to reflect unduly the interests and views of a single class. This interpretation has been expressed most forcibly by Thorstein Veblen. The greater gifts to American higher education have, however, usually been notably exempt from formal restrictions upon freedom of teaching; and in a number of privately endowed universities it has been better assured than in many state institutions. While ambitious administrative officers chiefly concerned for future endowments have not seldom imposed upon teachers in these subjects an unwholesome and unbecoming timidity and subservience, there are some indications that this condition is becoming more rare. Although exception must be made of certain sections of the country, it is probable that in the greater part of the United States, at the close of the third decade of the twentieth century, freedom of thought and speech in universities is growing wider and less insecure. The price of liberty is, however, the same in universities as elsewhere.

ACADEMIES. See LEARNED SOCIETIES.

ACCEPTANCE. The acceptance of a bill of exchange is defined in the Uniform Negotiable Instruments Law as "the signification by the drawee of his assent to the order of the drawer." It is the drawee's adoption of the bill or draft as his obligation, without which the instrument is no contract of his. The acceptance must be in writing and must be signed by the drawee. Acceptance is appropriate or necessary only in the case of time bills, as contrasted with demand or sight bills; but the certification of checks should be noted as an exception to this statement. The word "acceptance" is also used to signify the accepted bill itself.

A time bill drawn by the seller of goods upon the buyer thereof and accepted by the latter is known as a "trade acceptance." This is an important instrument of foreign and of domestic commerce, and in this country today such bills are being drawn and discounted even where seller and buyer are in the same city.

The time bill drawn upon and accepted by a bank gives us what is known as a "bank acceptance." Bills drawn upon and accepted by "acceptance houses" and "acceptance corporations" are for most purposes classified with bank acceptances. There is now at all times a tremendous volume of bank acceptances outstanding in this country. They are created to finance the movement or sale of goods in both our foreign and our domestic trade and are

utilized to some extent to finance for short periods the carrying of goods in warehouses.

The right of any person or company to draw a time bill upon a given bank is in no way founded upon the possession of a deposit with that bank, but is created by a special arrangement which pertains to some particular mercantile or financial transaction or to a series of such transactions. The authority which the bank confers upon the accommodated party to draw the time bill is very commonly evidenced by a letter, which usually takes the form of the so-called commercial letter of credit. It is understood that the accommodated party or parties will before the maturity of the acceptance supply the bank with the funds necessary to discharge the instrument, and that they will pay the bank a commission. The normal arrangement will provide in one manner or another for the pledge of the goods involved in the case to the bank as collateral security during the time running between the acceptance of the draft and the bank's receipt of funds for payment thereof, that is, the time through which it carries a risk. The bank does not lend any funds of its own and it does not receive any interest on money. What the bank does is to lend the strength of its name and take a risk of the failure of the accommodated parties to provide funds for the discharge of the acceptance at maturity, and it receives a commission which is chiefly a reward for this risk taking. The drawer of the bill obtains cash for the same by discounting it with some bank or broker. American banks often discount and rediscount their own acceptances.

Before the establishment of the Federal Reserve Banks the time bill was very little used in the domestic commerce of the United States. When a negotiable instrument did arise out of a mercantile transaction it would be the buyer's promissory note made payable to the one who had sold him goods on time. But since 1913 and especially since the conclusion of the Great War there has been an immense development in the use of time bills (and thus of course of acceptances). This movement was stimulated by the strong and persistent advocacy of the use of the instrument by a group of bankers and business men organized under the name of the "American Acceptance Council." The Federal Reserve Act affected this development (1) by making clear the legal right of national banking corporations to serve as drawees and acceptors of time bills (a right called in question by the decision of a lower federal court at an earlier time) and

(2) by giving the accepted bill of exchange a favored position over the promissory note, among instruments eligible for purchase by the Federal Reserve Banks. This country now affords a large and stable discount market for acceptances, and it is evident that this market will be permanent. The acceptance business of banks and of acceptance houses is older in Europe than in the United States and has flourished especially in England.

ACCIDENT INSURANCE. See COMPENSATION AND LIABILITY INSURANCE.

ACCIDENTS of all sorts took about 96,000 lives in continental United States in 1928, according to the estimates of the National Safety Council. Accidents in that year ranked seventh among all the causes of death, following close after pneumonia and tuberculosis. The accident death rate was in 1927 over two and one half times as great among males (112.3 per 100,000) as among females (43.6 per 100,000). In contrast to the principal diseases whose incidence is much heavier in later life, the accident death rate varies relatively little for the various age groups. Thus among children from five to fourteen accidents as a cause of death surpass not only any one disease but any two diseases. In the five to nine age group automobile accidents alone caused more deaths in 1926 than any one disease.

The trend of the accident death rate during the present century and especially during the past fifteen years has been on the whole slightly downward, but the decline has not been nearly so rapid as in the case of such diseases as typhoid fever, smallpox and tuberculosis. While the death rate from a considerable group of these diseases declined over 50 percent between 1913 and 1927, the accident death rate during the same period showed a net decline of only 7.4 percent.

This decline has been accomplished in the face of a rapid and serious increase in automobile accidents. Table 1 gives the comparison of death rates in 1911 and 1927, from Census Bureau figures, for the more important types of accidents. Each item shows a decrease, sometimes as great as 50 percent, with the exception of automobile accidents, which were multiplied almost ninefold. This multiplication has been due of course to the great increase in automobile traffic.

Vital statistics offer no separation between industrial and non-industrial or "public" accidents. The sub-classification afforded by the International List of Causes of Death relates rather to the type of accident, as shown in Table 1. From other data it has been estimated by the National Safety Council that of the total of 96,000 deaths in 1928 one fourth, or about 24,000, occurred in industry, leaving about 72,000 to be classed broadly as "public," including some 24,000 in the home, 27,500 in automobile accidents and the remainder from miscellaneous causes in public places, such as drowning, fire, falls and the like.

The number of accidents causing non-fatal personal injuries can only be roughly estimated by applying the ratios which have been found to exist in certain localities or groups. Table II sets forth the estimated non-fatal injuries, as well as fatalities in the public, home and industrial groups, together with similar estimates of the direct economic cost.

As the classification of accidental deaths based on the International List of Causes of Death is so unsatisfactory from the point of view of prevention, various efforts are now being made to improve the statistical knowledge of accidents. The standard death certificate is being altered to show in all cases of accidental death whether the accident occurred at home, in industry or in a public place, and to show also something of its nature. In addition an increasing number of state and city vital statisticians are using a supplementary form to obtain still further needed information regarding the circumstances of accidental deaths. Detailed information for non-fatal as well as fatal accidents is being collected by certain state motor vehicle bureaus, city police departments and safety councils, as well as by labor departments and individual industries.

The accident problem, although serious, is now no more so and probably less so than in earlier decades or centuries. Our machine age

TABLE I

ESTIMATED ACCIDENTAL DEATHS IN THE UNITED STATES, AND DEATH RATES 1927 COMPARED WITH 1911

TYPE OF ACCIDENT	NUMBER OF FATALITIES 1927 *	DEATH RATES PER 100,000 U. S. REG. AREA		
		1927	1911	PERCENT CHANGE
Accidental and unspecified external causes	93,127	78.4	84.7	—7.4
Burns (conflagration excepted)	6,669	5.6	7.7	—27.3
Accidental drowning	7,991	6.7	9.4	—28.7
" shooting	3,060	2.5	2.2	+13.6
" falls	16,596	14.0	15.0	—6.7
Mine accidents	2,940	2.5	3.8	—34.2
Machinery accidents	2,326	2.0	2.1	—4.8
Railroad accidents	7,549	6.4	13.0	—50.8
Collision with automobiles	1,836	1.5
Other railroad accidents	5,713	4.8
Street car accidents	1,590	1.3	3.2	—59.4
Collision with automobiles	521	0.4
Other street car accidents	1,069	0.9
Automobile accidents (excluding collision with railroad and street cars)	23,176	19.5	2.2	+786.4
Injuries by vehicles (other than railroad cars, street cars and automobiles)	1,750	1.5	3.8	—60.5

Other external causes	18,900	15.9	17.0	—6.5

*Estimated for entire United States from U. S. Census Bureau data.

has introduced new hazards, but it has probably eliminated more than it has produced. Yet accidents and their prevention, both in and out of industry, are undoubtedly receiving much greater attention today than ever before. The reasons are both altruistic and economic. This change in our national attitude toward accidents is quite in keeping with other trends of thought and action.

On the non-economic side the greater interest in the tragedies of accidental death or injury follows naturally upon the greater appreciation of the value of human life. Our increasing determination, as individuals and as a people, to reduce accidents is thus in step with our like determination to reduce diseases, prolong the span of life and generally ameliorate mortal ills rather than blindly accept them.

But in this industrial age the economic cost of accidents and the economic necessity of accident prevention are perhaps even more weighty. Not in industry alone are accidents now recognized as a definite and serious economic loss. An accident, wherever it occurs, represents an interruption of the orderly business of society. Death or disablement of the home keeper is just as much an economic loss to the family

and to society as death or disablement of the factory worker. Careful calculations have demonstrated the large economic investment in children of various ages as well as in adults, all of which is lost to society in the event of untimely death through accident. The medical and hospital costs of an accident are often heavy. And generally there are related costs such as property damage, loss of time by associates and other losses growing out of the interruption. In fact for every accident causing death or personal injury there are several which cause a measurable economic loss without personal injury. Rarely are these costs met by any sort of compensation or insurance (and

TABLE II
ESTIMATED ACCIDENTS AND THEIR COST, UNITED STATES, 1928, BY LOCATION*

TYPE OF ACCIDENT	FATAL	NON-FATAL PERSONAL INJURIES	ECONOMIC LOSS†
Motor vehicle	27,500	950,000	\$900,000,000
Other public	20,500	2,000,000	} 850,000,000
Home	24,000	4,800,000	
Industrial	24,000	3,200,000	1,000,000,000

*Estimated for entire United States from reports made to the National Safety Council.
†Economic loss from fire is estimated at \$550,000,000 additional.

when so, the cost is only passed on or distributed). Generally the expense must be absorbed by the individual or family budget, often entailing the most serious sacrifices. In other cases the financial and mental strain of a serious accident pushes the family over the line into temporary or permanent dependence, and society must pay the bill. In some cities careful studies have indicated that accidents cause as high as 17 percent of the total community cost for social service and relief.

Accident prevention is more possible in a controlled world. We have to a large extent learned how to avoid losses of life and injuries from the forces of nature. While these gains have been partly offset through the development of man made hazards, such as the automobile, it is possible to control these also—witness the decline in railroad accidents as shown in Table 1. And if accident prevention is more possible in a controlled world, it is equally true that in such a world the high cost of accidents and the need for accident prevention are more apparent and more keenly recognized.

The remedies for accidents of any sort fall into two main divisions: first, improvement of the environment, or removal of physical hazards; and second, improvement of personal practises, which is to be sought through a combination of education and supervision. Thus the prevention of traffic accidents means better streets and highways, better vehicles, better traffic control systems; education of all street users to understand the hazards of the street and to avoid them through care and law observance; and, finally, proper law enforcement for the recalcitrant minority. In exactly the same way the avoidance of home accidents means keeping home equipment in safe condition, educating both children and adults to the proper use of home equipment and the avoidance of unsafe practises and, finally, supervision of children especially to make sure that these precepts are carried out. And both these cases are parallel to the necessary combination of engineering improvement, education and supervision in industry. It is through such measures that accidents have been reduced and almost eliminated in numerous cases, and it is through similar measures that the present toll must be cut down.

ACCIDENTS, INDUSTRIAL. The subject of industrial accidents covers the occurrence of unforeseen or unexpected happenings in industry causing death or injury to persons employed or occupied, together with their causes and prevention. The present article is limited primarily to manufacturing industries; for other types of industrial accidents see MINING ACCIDENTS, RAILROAD ACCIDENTS and MOTOR VEHICLE ACCIDENTS.

The importance of industrial accidents may be illustrated by estimates of their numbers and of the economic losses which they produce. In the United States in 1919, it was estimated, there were 23,000 fatal accidents in industry, 115,000 accidents causing permanent total or partial disability, and 3,000,000 accidents causing disability of one day or more. These figures, together with the standard equivalents in time loss (see Table 1) in cases of death and total disability, were used as the basis for an estimate of 296,000,000 days of lost time due to industrial accidents.

The wage loss was estimated, on the basis of an average of \$4.00 per calendar day, at a total of \$1,184,000,000. If the cost of subsistence of the men killed be deducted, and the costs of medical service and insurance overhead, amounting to an estimated \$161,000,000, be added, the net economic loss due to industrial accidents reaches the figure of \$1,014,000,000. In this sum no allowance is made for discounting. Actually the accidents that occur in a given year cause losses which in cases, for example, of permanent total disability run far into the future. If in figuring the total losses from accidents which occur in a given year an allowance is made for discounting the value of these future losses to the date of the accident in all cases, the net total loss is reduced by about one third, or roughly to \$675,000,000. This represents approximately the annual losses from accidents in the United States.

The hazard of industry, or the frequency of accidents to persons employed or occupied in industry, is a concept capable of statistical measurement. In many industries, such as coal mining in gaseous mines, airplane transportation and deep sea fisheries, the presence of risk can

be recognized without elaborate statistics. Publicity given to accidents in these industries forms the basis for a popular estimate of risk. But a true picture of hazard can be given only by statistics of accidents placed in relation to the number of persons exposed to risk. The gathering of data on these points is comparatively recent; it is only within the past half century that it has been done, usually in connection with the administration of workmen's compensation laws for alleviating the consequences of industrial accidents.

Injury or death to the person, rather than the "accident," is the primary unit for measuring industrial hazard. Thus mass accidents or catastrophes in which many persons lose their lives or suffer serious injury are counted in the statistics not as a single accident but as injuries or fatalities to the number of persons involved. An "accident" in which no one is injured or killed is not counted in statistics of industrial accidents, although separate data on such accidents are available for railroad operation. Such occurrences may involve considerable property damage, but their omission from the statistics of injuries is necessary in order not to confuse the significance of industrial hazard. The data obtained as statistics of injuries, their causes and prevention are doubtless equally valid for all accidents.

Injuries caused by accidents are of different degrees of severity, ranging from the slightest abrasion of the skin to total disability or death. The number of trivial injuries, as already indicated by the estimates quoted, is of course far greater than the number of serious injuries. In the statistics, accordingly, minor accidents are omitted. In the larger number of states of the United States the recommendation of the International Association of Industrial Accident Boards and Commissions is followed, according to which injuries are tabulated if they caused lost time extending beyond the day or shift during which the accident occurred. In some states only accidents causing loss of time of a week, or even two weeks, are counted. In others accidents are tabulated only if compensable, that is, only if the loss of time exceeds the minimum waiting period, which may vary from three days to two weeks or more. These differences in definition of accidents which figure in the statistics are a cause of serious difficulty in statistical comparisons of industrial hazards in different states or countries.

The simplest method of stating industrial

hazard is to measure frequency of accidents in relation to the average number of employees exposed to the risk of accident. As already noted, minor injuries causing no lost time beyond the day of the accident are omitted. Even when these are omitted, however, the great number of relatively insignificant injuries means that such a rate is largely controlled by their frequency. This difficulty can be avoided in two ways.

In the first place, special rates can be framed on the basis of particular classes of disability: a frequency rate for fatal accidents; another for permanent total disability; a third for permanent partial disability; and a fourth for temporary disability. In this way the total accident frequency rate is split up into various components, each fairly comparable with other similar rates, except the fourth, which depends upon the definition of minor accidents included

TABLE I
SCALE OF TIME LOSSES FOR WEIGHTING INDUSTRIAL
ACCIDENT DISABILITIES

NATURE OF INJURY	DAYS LOST	DEGREE OF DISABILITY IN PERCENT OF PERMA- NENT TOTAL DISABILITY
Death	6,000	100
Permanent total disability	6,000	100
Arm above elbow, dismemberment	4,500	75
Arm at or below elbow, dismemberment	3,600	60
Hand, dismemberment	3,000	50
Thumb, any permanent disability	600	10
Any one finger, any permanent disability	300	5
Two fingers, any permanent disability	750	12½
Three fingers, any permanent disability	1,200	20
Four fingers, any permanent disability	1,800	30
Thumb and 1 finger, any permanent disability	1,200	20
Thumb and 2 fingers, any permanent disability	1,500	25
Thumb and 3 fingers, any permanent disability	2,000	33½
Thumb and 4 fingers, any permanent disability	2,400	40
Leg above knee, dismemberment	4,500	75
Leg at or below knee, dismemberment	3,000	50
Foot, dismemberment	2,400	40
Great toe, or any 2 or more toes, any permanent disability	300	5
One toe, other than great toe, any permanent disability	0	0
One eye, loss of sight	1,800	30
Both eyes, loss of sight	6,000	100
One ear, loss of hearing	600	10
Both ears, loss of hearing	3,000	50

in the statistics. In comparisons between countries these rates are often more useful than the total frequency rates.

Secondly, a composite rate may be formed by weighting the accidents in accordance with their severity. The most feasible (and most used) method is to weight accidents in proportion to the actual time lost; except that in case of death, permanent total disability and specific types of dismemberment accidents are weighted according to a standard weighting system which places a due weight upon these serious injuries. Table I gives the standard weights adopted by the International Association of Industrial Accident Boards and Commissions, which are used by the United States Bureau of Labor Statistics in its accident severity rates. In this system a death or total disability is weighted with 6000 days lost time, on the assumption that the average loss in such cases is equivalent to twenty years of three hundred working days each, while the weight assigned for the loss of a hand is set, perhaps somewhat arbitrarily, at 3000 days. Severity rates, as thus calculated, measure industrial hazard in terms of days lost as compared with the time at risk.

In all these rates the basis or "exposure" is of fundamental importance. The total number of workers is less satisfactory than the average number of workers employed, since the latter gives a truer measure of exposure; and furthermore, because of differences in hours of labor in different industries and at different times, even the average number of employees is a relatively poor method of measuring exposure. Obviously the longer the working hours, other things being equal, the greater the number of accidents. In order, then, to allow for differences in hours of work between different establishments or different industries, and particularly in order to measure gains in reduced accident frequency due to decreases in hours of labor, the denominator of the rate fraction must take account of the total hours of employment. Accordingly, in careful accident statistics, frequency and severity rates are expressed in terms of hours of employment, e.g. in terms of 1,000,000 or 1000 hours (as in the rates of the United States Bureau of Labor Statistics) or in terms of the number of "full time workers," that is, a worker working 300 days a year, 10 hours a day, or 3000 hours (as in German accident rates).

Turning to the statistics of accidents in industry, Table II presents, for eleven states,

accident frequency and severity rates by industries for the year 1925. Frequency rates (accidents per 1,000,000 hours exposure) varied from 1.96 in the manufacture of woolen goods to 59.08 in the manufacture of automobile tires. Severity rates (days lost per 1000 hours exposure) ranged from .32 in the boot and shoe industry to 4.85 in the paper and pulp industry. Among the more hazardous manufacturing industries were structural iron work, lumber planing mills, lumber saw mills and flour mills. Among the least hazardous were the manufacture of woolen goods and the manufacture of stamped and enamel ware. The rates for a single year, however, are not always significant of permanent conditions, since they may be affected or determined largely by unusual conditions.

The most extensive analysis of hazard in any American industry is that of the iron and steel industry made by the United States Bureau of Labor Statistics. This analysis extends over a period of twenty years. The hazards of the industry are analyzed according to the department of work and, to a limited extent, according to occupation, age and other personal characteristics. Subjoined is a table showing variations in accident frequency and severity rates in the iron and steel industry from 1907 to 1925.

The analysis shows striking differences between different departments in the iron and steel industry. Frequency rates per million hours exposure for 1921-1924 varied from 17.0 in Bessemer converters to 63.1 in foundries, while severity rates for the same period ranged from 1.9 days lost per thousand hours of exposure in sheet mills to 4.6 in blast furnaces.

The record of improvement in accident frequency and severity is brought out clearly in this table. In the department of Bessemer converters the frequency fell from 101.5 in 1907-1910 to 17.0 in 1921-1924, a decrease of over 80 percent. In foundries, however, little or no change has been manifest. In heavy rolling mills a decline of 70 percent has been attained. In sheet mills a decrease of over 25 percent has been noted. Decreases in severity rates are somewhat less marked. This is especially true of Bessemer converters, where the decrease in severity rates was only slightly over 50 percent as compared with an 83 percent decrease in the frequency rate.

Comparisons between the two parts of the steel industry are significant of the influence of preventive work. The average accident fre-

quency and severity rates in that part of the industry which is engaged in active safety work are approximately one fourth those in the other part. How striking was the decrease in accident frequency rates in the former division can be learned from Table IV. An average frequency rate of 60.3 accidents per million hours exposure for the year 1913, for example, decreased for the year 1925 to 8.2, a decrease of over 85 percent. An analysis of the rate by causes permits us to judge how evenly the decline was distributed among the component parts of the rate.

† Less than one tenth of one.

Accident frequency and severity rates are available in detail for a few industries outside the iron and steel industry. The United States Bureau of Mines compiles accident frequency rates in metallurgical plants. In 1924 frequency rates per 1000 hours exposure were 52.42 for ore dressing plants, 37.73 for smelting plants and 46.17 for auxiliary works. For fatal injuries the frequency rates were .41, .18 and .36 respectively.

For certain establishments associated in the National Safety Council accident experience by industries is available. Frequency and severity rates in thirteen principal industries in 1925, based upon conditions in 1231 establishments represented in the National Safety Council, are given in Table V. The average accident frequency rate for all these establishments was 30.60 (per 1,000,000 hours) and the average severity rate was 2.02 days lost per 1000 hours worked. The lowest rates were in the textile industry, with a frequency rate of 13.61 and a severity rate of .45. In this industry only one accidental death occurred in 77,924,601 hours of employment. The highest rate (except that of 99.99 in mining) was 69.54 in construction (with a severity rate of 7.57). Since the establishments included in this experience are all actively interested in safety work, it is probable that these rates are lower than the average for the industries as a whole.

Next to the study of industrial accidents in the United States, that in Germany is of

has been the development of reasonably accurate accident frequency rates.

Table VI shows accident frequency rates per 1000 full time workers in a number of German industries. These rates are not statistically comparable with those already presented for the United States, since in Germany accidents causing less than thirteen weeks disability are cared for by the sickness insurance institutions, while only those causing disability exceeding this period are counted in the statistics of cases cared for by the accident insurance funds. In any case the differences in the basis of calculation in terms of (per 1000) full time workers

* Source: Supplement to the 75th Annual Report of the Registrar-General for England and Wales, part iv, "Mortality of Men in Certain Occupations in the Three Years, 1910, 1911, and 1912" (London 1919) p. xxii-xxiv.

† Calculated by applying to a standard male population 25 to 65 years of age the actual accident mortality rates in the specified occupation, the average rate from accident for all occupied and retired males 25-65 yielding 47 deaths when applied to this standard population. See reference for details of its construction.

(i.e. per 3,000,000 hours) should be noted. The chief value of these figures is for comparing different industries, and for this purpose rates for mining, transportation and agriculture are included in the table. Frequency rates are shown also for fatal cases, for total disability and for partial disability.

The statistical record of accidents in Germany shows a very marked decrease in accident frequency rates in the forty years during which the insurance system has been in operation. The number of fatal accidents, for example, per 1000 insured workers in industrial corporations decreased from .77 in 1887 to .47 in 1926. The frequency of accidents involving total permanent disability similarly decreased from .73 in 1887 to .05 in 1925. The figures for temporary disability are not of special significance because of the tendency of rates to increase owing to improved reporting of accidents.

An alternative method of throwing light on industrial hazard is through the study of mortality from accidental causes, classified by occupations. Although these figures include accidents not only from industrial but from other causes as well, industrial hazards are the chief factor in producing differences in accident mortality for persons in different occupations.

The only satisfactory statistics of occupational mortality on the basis of which industrial hazard can be measured are for England and Wales. Statistical analyses, made every ten years since 1890, show the relative importance of accidents as a factor in mortality in different occupations. A selection of hazardous and non-hazardous occupations with their comparative mortality from accidents according to the latest available figures, those from 1910-1912, are given in Table VII.

The distribution of accidents according to degree of disability and severity of the injury caused, as already suggested, is fraught with some difficulty on account of the variable definitions of the accidents which are in practise included in the statistics. Especially in case of minor accidents are the statistical differences likely to produce differences in their apparent frequency. For purposes of presenting a fair picture of the relative frequencies of fatal accidents, those causing permanent disability and those causing temporary disabilities over varying lengths of time, the standard accident table compiled by Dr. I. M. Rubinow is presented in slightly abridged form as Table VIII. This table is based upon a careful analysis

and comparison of the available statistical materials on the severity of industrial injuries in the United States and European countries.

TABLE VIII

DISTRIBUTION OF 100,000 ACCIDENTS ACCORDING TO DEGREE OF DISABILITY CAUSED *

DEGREE OF DISABILITY	NUMBER OF ACCIDENTS
Fatal	932
Dismemberments	2,323

The causes of industrial accidents are a primary object of inquiry. The conception of cause has undergone considerable modification. Early ideas of responsibility led to a classification according to the responsibility of employer and of employee, with a considerable residuum of accidents attributed to the general hazard of the industry. The fundamental idea that lies

back of the present day analysis is prevention. In the United States the basis of classification by causes has been studied by a committee of the International Association of Industrial Accident Boards and Commissions, whose classification scheme has been adopted by the United States Bureau of Labor Statistics and by a considerable number of states. The League of Nations has published the cause classification schemes used in various countries.

Details regarding the principal causes of accidents in the steel industry in the United States have already been furnished in Table iv. This indicates the general character of the cause classification. In other industries the various causes are, of course, of varying importance; each industry needs special data on causes in order to ascertain the direction in which preventive efforts should be turned.

Table ix shows the relative importance of the several causes in seven European countries and in two states of the United States. The marked variations in the percentages of accidents caused by machinery, for example, may be due to differences in the relative importance of mechanical industries, or to differences in the advancement of the safety movement, or perhaps to differences in the assignment of causes in classifying the statistical material.

In addition to causes, what may be termed "causal factors" are of great importance. These are of two groups—those concerning the workers and those concerning the work. Among the first are age and sex of the worker, his race or nationality, his mental and physical condition, fatigue and his attitude toward his work; among the second are the length of the work day, speed and intensity of work, and provision of rest periods. Space is lacking to do more than suggest lines of investigation in two or three of these topics.

Special studies have been made of the influence of fatigue upon the causation of accidents. Data on the relation between the occurrence of industrial accidents and the hour of the day in general show an increase in accidents during the morning hours to a maximum at about eleven o'clock, a falling off as the noon rest period approaches; and an increase during the afternoon to a maximum for the day a short time before the end of the afternoon's work. This analysis indicates that fatigue, though perhaps not the sole element in the situation, is probably an important factor in the rising frequency rate of accidents during the progress of

the day's work. A study of the relation between accidents and fatigue was made by the U. S. Public Health Service during the war period in the form of a comparison between the frequency of accidents in an eight-hour and in a ten-hour plant. In this study the frequency of accidents was measured not only in terms of time of work but also in terms of output. Important studies of the relation between accidents and fatigue have been made during and after the war by the Industrial Fatigue Research Board in Great Britain.

Statistics on the relation between age and frequency of accident are available for German experience, and indicate that accident frequency rates increase with age.

TABLE X

ACCIDENT FREQUENCY RATES BY AGE AND SEX,
GERMANY, 1897 *

So far, however, as the liability of accident of young persons just commencing work is concerned, such figures are inconclusive, because the occupations in which young persons are employed are often not of the same character as those in which older persons are engaged. Employment of children in dangerous occupations is prohibited. Lower frequency rates for young persons may thus indicate simply the greater safety of the types of occupations in which they are predominantly engaged.

That physical or mental ill health is a frequent cause of accidents needs no statistical proof; but statistical evidence is lacking because of the difficulty of obtaining data on exposure and on accidents classified in comparable fashion as to condition or type of sickness.

Prevention of accidents and minimizing their

consequences through prompt first aid are the primary objectives toward which both statistical analysis and safety work are aimed. Theoretically, at least, all accidents should be prevented. A study of the magnitude of the problems emphasizes the need for prevention, and a study of the causes of accidents and of the conditions that produce them points the way to methods by which they can be prevented.

Methods of prevention may be directed toward removing a specific cause, bettering or remedying a condition that favors accidents, or stimulating and promoting safety. Responsibility for making industry safe is most effectively placed with the management; this responsibility is in practise made effective by shifting the burden of cost of workmen's compensation to employers. Insurance companies assist in promoting safety through inspection and through rating systems. The actual introduction of methods of prevention is a matter for the technical expert or safety engineer.

A large group of accidents caused by machinery can be prevented by designing machines so as to eliminate the source of danger. Guards are introduced to cover exposed moving parts, to enclose gears, belts and moving chains, so that workers are unable to place their hands in places where they can be injured. Laws to require the provision of machine guards have been generally enacted, and are enforced by routine inspection. Commissions have been set up with administrative power to issue safety regulations. Such regulations are for the most part directed toward the provision of safe work places, although in certain cases unsafe practises of employees are forbidden.

A striking development of recent times is the organization of safety departments in industrial establishments. These departments are charged with responsibility for preventing industrial accidents. They are commonly placed in charge of safety engineers who study the causes of accidents and introduce methods of eliminating and preventing them.

A second direction of effort involves the systematic study and elimination of points of hazard throughout an entire establishment. The manner of routing supplies, of placing machinery with reference to the location of aisles, the quality of illumination, the use of motive power, the substitution of electrically driven single unit machines for the older type of machines driven by exposed belts, are all studied with reference to the possibilities of

reducing accidents. In building new establishments, in particular, the layout of the plant is planned with especial reference to eliminating hazards.

These methods of prevention call for technical skill. Each type of machine may require some special device to render it safe. In using electric power automatic devices are required to cut off the electricity before repairs can be made on the machinery. Elevators require special safeguards. The various devices that have been developed for different specific hazards are illustrated in exhibits at safety museums.

Another method of prevention is the provision of special clothing to guard against particular types of hazards. The wearing of goggles with non-splinterable glass is necessary in occupations where workers are exposed, as in work in foundries, to flying particles of metal. Another illustration is in the use of shoes which can be slipped off immediately in occupations in which workers are exposed to splashing molten metal.

Another type of preventive effort is directed toward the education of employees in safety practises and toward stimulating them to cooperate with employers in reducing accidents. These educational campaigns include safety talks for workmen and foremen, and utilize posters and various types of educational material. In particular they make use of the spirit of rivalry in different departments of the establishment or in different establishments in order to obtain the best record in safety.

Personnel selection may be used to reduce accident frequency. Physical examination of workers with special reference to their liability to particular types of accidents is an important method. In railroad operation the elimination of color blind engineers and firemen is a familiar illustration of this type of personnel selection. The examination of employees with reference to their physical condition may extend also to temporary illnesses, and it may provide that employees who are not up to their normal physical standard of health shall be excused from their usual occupations where these involve any considerable degree of risk.

The training of workers in the special requirements of their work is an important method of accident prevention. Records indicate that an unusual proportion of accidents occur within the first few days after a worker begins work on a new type of machinery. In other words, during

the learning process accidents are frequent. If a sufficient training period is allowed, the frequency of accidents during this initial stage may be materially reduced. Careful personnel work includes fitting employees to their positions, providing suitable rest periods and, if necessary, psychiatric treatment to produce the best adjustments.

An important question relates to the proportion of accidents which are preventable. Recent estimates by Sidney J. Williams put preventable accidents at 75 percent. These estimates are supported by the experience of various industries in reducing accidents with the introduction of safety work. For example, in establishments in the steel industry the accident rate has been reduced 75 percent since undertaking systematic safety work.

A study made by the Travelers Insurance Company suggests that 98 percent of all accidents can be prevented. This estimate is reached on the basis of an analysis of a considerable number of accidents. It was found that in practically all cases the accident could have been prevented if the employers had been held responsible for introducing known methods of prevention, including close and watchful care over the physical and mental condition of their employees. In support of this view that practically all accidents can be prevented certain remarkable records for safe operation of industry can be cited. One record is of ten million hours of employment without a lost time accident. Other long runs have been made by enlisting the cooperation of employees in the prevention of accidents. Accidents can be prevented by eliminating all hazard producing causes and conditions in industry, using methods suggested through careful study.

ACCLIMATIZATION is the process by which an organism becomes adapted to a new climate. The test of acclimatization is not the survival of the individual, but of the species or variety. Acclimatization occurs frequently among plants and animals, as appears in the fact that wheat, potatoes, horses, hens and many other species thrive in climates very different from those where they originated. The same is true of man; early man almost certainly migrated into many climates and then became acclimated; modern man is doing likewise. Acclimatization is often accompanied by changes which adapt the organism to the new environment, e.g. the shaggy coat and small size of Shetland ponies, the hairiness of mountain primroses, and the colors of the human skin and hair.

Acclimatization depends upon two fundamental laws. First, every species is subject to climatic limits imposed by temperature, humidity, sunshine, wind and other factors. Within certain limits the individual can survive; within more restricted limits it can permanently reproduce its kind. Second, every species thrives best under definite conditions of climate. But the optimum for vegetative growth may differ widely from the optimum for reproduction. Moreover the optimum and the limits vary appreciably from one individual to another.

The physical optimum for Europeans involves a mean temperature of about 65° F. for day and night together; a relative humidity averaging about 80 percent; and an interdiurnal

variability averaging not far from 3° F. There is some evidence, although not conclusive, that under modern conditions of clothing and housing the optimum for mental activity is an outdoor temperature averaging not far from 40°. On this basis the optimum climate for the white man satisfies the following requirements: midday summer temperature from 70 to 75° F.; winter nights frosty; air moist enough to form dew or frost at night, and relative humidity at noon rarely below 50 percent; storms numerous so that weather is variable and average change of mean temperature from day to day is about 3°. Southeastern England approaches these conditions, but nowhere does the white race live under the absolute optimum of climate.

The main problem of acclimatization centers around the white man in the moister parts of the tropics. The permanent British settlers in northern Australia, the Americans in Hawaii, the Dutch in South Africa and Java, and the Spanish and Portuguese in Latin America are said to prove that white acclimatization in the ordinary sense is possible. Opponents of this view point out that Australia, Hawaii and South Africa are only sub-tropical, in Java there are very few Dutch children of the third generation, while in Latin America people of pure European descent are rare outside the cool highlands and even those few are dark skinned.

The Australian studies of Sundstroem probably indicate the real truth. Among healthy white people living permanently on the edge of the tropics he found that the composition of the blood and the general functioning of the system differ slightly but systematically from those of the white people in cooler climates. Practically all students of the problem agree that life in the tropics tends to produce nervous instability—neurasthenia—among white people. Such conditions do not necessarily prevent the production of healthy children, but they appear to induce a state of physiological stress, and presumably decrease the resistance to disease although this has not yet been demonstrated. More extreme conditions of the same kind doubtless prevail where the climate is more steadily warm and moist. Whether they would prevent the rearing of healthy children if tropical disease were eliminated, no one yet knows. The Japanese reactions to climate are almost identical with those of Europeans. It may be significant that in September at the end of the hot, damp, debilitating summer, which

simulates a tropical climate of the more humid type, the conceptions that give rise to living children in Japan, where there is no birth control, are only a little more than half as numerous as in June, and are fewer than the deaths. Moreover, even though tropical diseases may be eliminated among selected groups of both whites and natives, their general elimination among the hundreds of millions of tropical natives is at best a matter of many generations.

The diversity of opinion as to tropical acclimatization arises partly from failure to appreciate natural selection. Constitutional peculiarities, both physical and temperamental, permit some persons to thrive under temperatures and humidities which are almost intolerable to others. Among the thousands of people who contemplate a tropical sojourn, the health or temperament of themselves or their families reduces the sojourners to hundreds, while only tens remain permanently and few of those have families. Thus the white parents who bring up families in moist tropical climates are a very highly selected group. They either possess peculiarly vigorous, adaptable constitutions, or have climatic optima which tend toward the tropical type. Yet even their descendants are weeded out very actively by death, sterility or migration. Thus a healthy European child of the third generation in the tropics represents a highly extreme type and is no indication of what might happen to large groups of people under similar conditions. Even if tropical diseases should everywhere be conquered and the most rigid selection should segregate a fairly well acclimated white stock, we do not yet know whether the vigor of such a stock would equal that of the ordinary stocks in cooler climates.

ACCOMMODATION is to be differentiated from adaptation, although both are forms of adjustment. If adaptation is defined as structural changes in the organism which take place through biological variation and selection, the term "accommodation" may be reserved for functional changes which take place in the habits and customs of persons and groups and which are socially rather than biologically transmitted. This distinction between biological and social adjustments was first made by J. Mark Baldwin, who perceived in accommodation the process by which "old habits are broken up, and new coordinations are made."

Franklin H. Giddings appears to be the first social scientist to make systematic use of the term accommodation, although in the limited sense as one among several modes of the universal method of conflict. Gabriel Tarde employed the term to denote the resolution of the conflict between two opposing ways of acting and the emergence of a new pattern of behavior. Georg Simmel, without himself using the term, described and analyzed the process of accommodation in its interrelations with the process of conflict. Robert E. Park and E. W. Burgess place accommodation with competition, conflict and assimilation as the four chief processes of social interaction. They point out that these social processes tend to create different types of social order: competition resulting in the economic equilibrium; conflict, in the political order; accommodation, in social organization; and assimilation, in personality and the cultural heritage.

Social organization is the sum total of accommodations to past and present situations. All the social heritages, traditions, sentiments, culture, technique, are accommodations; they are acquired adjustments that are socially and not biologically transmitted.

Historical societies have been organized around different forms of accommodations such as slavery, caste and classes. These types of social organization involve different patterns of social adjustment between dominating and subject groups. Stages in accommodation to conflict situations may be arranged in a series as follows: domination, toleration, compromise, conciliation and conversion. A *modus vivendi* is a special form of accommodation whereby persons or groups in conflict are enabled to carry on certain necessary activities without resolving the points in dispute.

Accommodation groups, organized to articulate with the environing social order, like clubs, social classes and vocational groups, castes, denominations and nations, are to be differentiated from groups organized for conflict, such as gangs, labor organizations, employers' associations, and middle class unions, races, sects and nationalities. The transition from a gang to a club, from a sect to a denomination, and from a nationality to a nation, discloses the process by which a group achieves equilibrium in its milieu.

The equilibrium maintained by accommodation, whether in a society, group or person, has been subjected to internal as well as external description and analysis. Simmel's statement of the reciprocal nature of superordination and subordination; Moll's study of rapport; the essays of James and others upon religious experience; the development of the concept of sublimation—all indicate the insight to be secured by research upon the role of attitudes in the process of accommodation. Life histories and personal documents are found to be valuable materials for research on the original conditioning and subsequent changing of attitudes involved in accommodation. Attitudes of race prejudice, of superiority or inferiority, and of loyalty may be transmitted to the members of a group by tradition, or they may be the outcome of certain crucial experiences of persons or groups. Changes in attitudes in the process of social adjustment to new situations may take place suddenly or gradually. Mutations, or sudden accommodations, occur under crisis situations, such as invention, migration, disaster. Gradual accommodations are the less perceptible changes seen in the process of acclimatization, naturalization and of maintaining equilibrium.

Accommodation, or the process of making social adjustments to conflict situations by maintaining social distances between groups and

persons which might otherwise come into conflict, is to be differentiated from assimilation, which is the process by which cultures and personalities interpenetrate and fuse. An illustration is seen in the accommodation of the immigrant in his adoption of dress, food, habits and language, without himself fully participating in the cultural heritages and common purposes of his adopted country by which his children are assimilated. It follows that while assimilation takes place in situations of primary, personal and intimate contacts, accommodations typically are arrived at by formal and external arrangements.

The concept of accommodation has so far found its most fruitful use in studies of immigration, colonization and race relations. It will also be found of value in research in social conflicts, adjustments in labor problems, industrial relations, community organization and political parties, as well as in the study of the social psychology of subordination and superordination, social status, social types and leadership.

ACCOUNTING, in the broad sense of the term, includes all the business records kept by a business organization or unit of government, as well as the principles and technique involved in establishing and maintaining the records. It covers two general groups: first, statistics and memoranda relating to production, properties and other non-monetary quantities; and second, financial records representing investment, expenditures, receipts, fiscal changes and standing, expressed in monetary units. In the narrower sense, as ordinarily used and as treated in this article, it relates to the second class of records. The other records, however, are of great business and public importance; they are usually integrated with the more formal system of accounting dealing with financial categories. A modern railroad company, for instance, maintains in addition to records of

monetary transactions, records of service; physical operations, employees, materials, locations and changes of property.

HISTORY. The history of accounting reveals very clearly the constant interdependence of accounting knowledge and business requirements. Progress in the science and technique of accounting has made possible an increase in the size, complexity and territorial scope of business operations. Conversely, these business changes have spurred the advance in accounting knowledge and technique. The kind of records that are needed depends upon the business, but the kind of business that is possible depends upon the records that can be kept.

Accounting goes back to the earliest times of doing business. The simplest of commercial transactions, repeated period after period, required some sort of record. The invention of the system of double-entry, which is fundamental to complete financial statements, cannot be definitely credited to any particular person. There is evidence that it was employed even during Phoenician, Greek and Roman commercial supremacy and it was extensively developed and applied during the great Italian commercial era of the fourteenth and fifteenth centuries. After commercial leadership passed to Holland and England, it was introduced and greatly developed in the accounting houses of the great trading companies. The system depended upon "hand" efforts, and became formalized as to procedure and related books. There was the "day book," which recorded all the business transactions in chronological order. From the day book the items were restated chronologically in the "journal," and analyzed into "debits" and "credits" by accounts. Finally, from the journal the items were entered in the "ledger" to individual accounts. Cross checks and balances were established to maintain accuracy of records. This mechanical system continued until the expansion of business that followed in the wake of the industrial revolution.

The new impetus started about 1840 in Great Britain with the organization of railroad companies and the great growth of manufacturing and trading concerns. It followed to the United States and other countries with the extension of large business organizations and has been hastened by mechanical inventions and cumulative business pressure. During the past fifty years the old formalism has been discarded in large business, but still prevails in smaller

undertakings. Short cuts and adaptations are employed according to possibilities and needs. Specialized records are provided as conditions require. The old day book has been replaced by various forms of original records, kept according to convenience. The formal journal remains only as a record of special accounting adjustments which do not represent original transactions. The old ledger is replaced by special ledgers, subdivided and grouped according to the needs of each organization. But underlying all the sub-ledgers and the various original and intermediary records, the old principle of double-entry controls. The various ledgers are so organized that they are finally brought together in a comprehensive whole, as represented periodically by the balance sheet and the income statement. In large businesses, moreover, there is usually a "general ledger" which is based upon the subsidiary ledgers; this usually preserves in a single book complete financial records of the business, including assets, liabilities and operations, and also contains the accounts which appear directly in the balance sheets and income statements. It is based upon double-entry, and serves as a "control" of the several subsidiary ledgers.

The development in accounting practise during the past fifty years has paralleled business development. The great size of business units has involved increasing complexity as to kind of activity, diversities of property and extent of territory, and the accounting systems have followed the organization of business concerns. Each managerial unit of a large corporation must be completely informed with respect to the properties and activities for which it is responsible. The head of the corporation must have before him such general accounts and records that he can maintain constantly a comprehensive grasp of the entire business, its financial standing, its operating activity, its costs and returns and the interrelation of the larger units. These general records must bring together the various departments, whether organized by functional or by territorial lines or by a combination of the two. Each department head must have similar records for his domain, which may represent both a territorial and a functional subdivision. Extending down the line, each unit head depends upon exact records to exercise control and to keep his part coordinated with the wide ramification of the business. Consequently the amount and variety of accounting work needed by a large

modern business concern are enormous. Modern accounting requires coordinated organization, expert division of labor, use of machinery and labor saving devices. It depends upon intricate equipment, mechanical billers, adding machines, typewriters, tabulators and classification machines. Without such facilities modern accounting would be impossible: the great bulk could not be handled, and the cost would be prohibitive.

Numerous special factors have influenced the development of accounting. With the growth of business, there has been increasing need of accurate records of physical property, particularly as operation has involved various kinds of property in large quantities, scattered over wide areas of territory. To meet this situation, continuous inventories have been developed and coordinated with the general accounting system. For manufacturing concerns, it has become increasingly necessary to have reliable cost records, both for the fixing of sales policy and for comparison of results between individual plants under the same ownership. Exact performance data are essential to furnish a gauge of the relative efficiency of plants or operating units. Statistical devices have been incorporated with the accounting system, to supply analysis, to furnish checks upon activities and to promote improved methods of production or management. With the fluctuations in prices or monetary values, it has become necessary for the management to know not only what its actual costs have been, but also what the present costs would be, and what the relative costs are between various units in different localities under the same control.

A large factor in modern accounting development has been the growing control of government over business. Detailed accounting classifications have been prescribed by government commissions for the utilities subjected to public regulations. The companies are required to file annual reports with the commissions, for which uniform provisions are made. Special tax reports are required for local, state and federal governments; the necessary data must be provided through the regular accounting channels. Through these and other relations to business, government has furnished a powerful spur to accurate accounting procedure, better classification and technique; if it has not actually originated new methods, it has exerted an influence in extending the best private practise to all business units in the same field.

While the modern tendency has been away from formalism, to adjust the accounting to business needs, there have been also strong forces for standardization and uniformity. In part, standardization has been promoted by the various governmental regulations. It has been stimulated even more by the demands for comparable data of trade and financial organizations, such as the stock exchange, financial publications, bankers, investors and trade associations. As business has become larger, its strictly private aspects have diminished, and its public character has been augmented. An underlying uniformity of classification has become desirable both as to property and other balance sheet accounts, as well as in respect to operating costs, sales, sources of revenue and other operating data.

Along with the vast extension of accounting practise, there has grown up an accounting profession, which has become variously specialized in fields of accounting investigation, analysis and system installation. Auditing firms, which are themselves organized businesses, make periodical investigation of the accounts of business houses required for a great many public and private purposes (see AUDITING). Accounting specialists have also become prominent in connection with various kinds of financial litigation which require technical knowledge and accurate analyses of costs, returns and operating results. Similar studies are made for the purpose of reorganizations, promotion of efficiency, and consolidations. They are required in wage controversies, especially before arbitrators or government bureaus, and are even more necessary in connection with utility rate controversies before the federal, state and local tribunals.

The profession of accounting has become established on a par with law, medicine and other learned professions. The varied accounting activities involve public interests and require assured ability, training and reliability. To safeguard the public, the accounting profession has become organized and regulated by law. Many countries have made provisions for certified or chartered public accountants, who practise within the requirements and protection of the statute, and have formed special organizations in the interests of accounting. Such regulations and organizations developed earlier in Great Britain, because of earlier business conditions requiring professional standards. In

Great Britain the profession was thus organized between 1850 and 1880, while in the United States corresponding organization was not started until about 1895, when the New York Society of Certified Public Accountants was established. In continental Europe the recognition of accounting as a profession was much slower in coming. Associations of accountants in these countries were local in character and intended primarily for the protection of common interests. Only after the World War has rapid progress been made and a semi-public status been granted to these associations.

Coincident with this rapid evolution in accounting, there has come a great intellectual interest in accountancy. This is indicated by the new type of books on accounting, by the special accounting journals, that have appeared and the character of articles published, by the numerous accounting materials contained in economic and financial publications, and especially by the inclusion of accounting studies in the educational system of the country. A generation ago, bookkeeping of a formalistic type was occasionally taught in the public schools, but was for the most part confined to the special "business colleges," which were generally of low academic grade. During the past generation, however, accounting has come to be a recognized department in every modern high school, and now appears in most of the colleges and universities as a part of the discipline for undergraduates who expect to enter general business. Schools of commerce with programs of study centered in accounting have emerged and grown with amazing rapidity in our large cities; graduate schools of business administration have appeared, and provide opportunities for an intensive study of accounting. In the graduate departments of our universities, accounting has become recognized as worthy of academic tolerance because of its effectiveness as a tool for economic research. Understanding of accounts is now a requisite of modern business preparation, not only for professional accountants, but also for business managers, bankers, lawyers, engineers, economists, in short all who must deal with costs, earnings, business affairs, governmental operations, and activities of public control.

THEORY. Although many old forms and conventions have been discarded, modern accounting is still based on the principle of double-entry, or that of an equation of financial trans-

actions. On the one side are all the so-called debits, and on the other all the credits; the sum of the first equals the sum of the second. The accounts are subdivided according to the needs and convenience of the business, but they always constitute a balancing equation.

When a business is first organized, the accounting begins with the receipt of money or other equivalent values invested in the undertaking. A double entry record is kept, first, of the money or other values placed in the enterprise, and second, of the source of the investment. There is an obvious equation; the amount of cash or other values received is debited to one account, or to a group of accounts, while the same sum is credited to the source or sources from which the values were obtained. The cash or equivalent values constitute assets or property of the business, and a separate record or account is kept of each class of assets. The original entry is a debit or charge to the appropriate asset or property account. On the other side of the equation, the same amount is credited to the particular source or sources from which the assets were derived. The accounts may be of individual owners; stockholders, common and preferred; or bondholders and other creditors who conveyed cash or other assets to the business. The sum of the debits thus represented by the various asset accounts is, necessarily, equal to the sum of the credits entered to the various groups from which the assets were obtained for the establishment and operation of the enterprise. Ordinarily, at the inception of a business, the assets are in the form of cash, and the source is represented by a single individual or by a small group. A modern corporation, however, may begin with a great variety of assets, already classified according to convenience, and with many sources from which the properties were derived. However simple or complicated the beginning, the results are the same: the asset or property values debited to the asset or property accounts are equal to the sums credited to the various sources from which the assets were obtained for the purposes of the enterprise.

After the inception of a business, the accounting is concerned, on the one hand, with recording the changes that take place in the various assets, and, on the other, with the changes in the sources or the relative rights in the assets. The cash with which the business starts is expended for other assets or property

required for operation. These changes must be recorded in the proper asset accounts as each is specifically affected. An addition to any particular class of assets is debited or charged to the particular asset account; the disposal of a particular asset is credited to the appropriate account; the difference between the debits and credits of any asset account is the balance of the particular asset in so far as it is represented in the total equation.

In regard to the original credits showing the sources of the funds contributed to the business and hence the rights to the assets, these accounts are ordinarily not affected by the transfer of assets that takes place in the course of operation. The sources or rights at the beginning are represented by owners or creditors, and they are subdivided according to individuals or groups. Each account starts with a credit entry; subsequently, as any change takes place, increases are credited, and decreases are debited. The balance of each particular source is thus shown at any time by the difference between the credits and the debits of the account, and in the total equation it is represented upon the other side by an equal amount of net assets.

The accounts which record the source of funds or interest in the business are usually termed liabilities. This is a comprehensive term, covering all accounts which normally show a credit balance at any particular time. It is used because of its convenience, and is fully understood by accountants; otherwise it might be misleading since it includes not only interests represented by actual liabilities or debts of the business, but also other sources, original capital contributions, reserves accumulated for various operating purposes and profits or surplus derived from operation. The term, however, has been established, and conveniently distinguishes the entire group of credit accounts from the asset accounts which show debit balances at any particular point of time.

The business starts with an equation stating the assets and the source of the assets. Every business transaction is subsequently recorded as it affects the various kinds of assets and the different sources, and thus constantly preserves the equation. All operations involve intrinsically an exchange of some assets for other assets, i.e., goods are bought and sold. There is thus a constant recording of the assets affected with purchases and sales; with every transaction the

proper asset accounts are debited and credited. The object, however, is to obtain more assets in each round of purchase and sale. This involves not only a mere change or turnover of assets, but also a net increase in assets, a new source element in the equation. The net increase in assets is represented by the profit or surplus, which constitutes a separate source or interest, and at any point of time appears as a net credit in the special account (or debit, if there is a loss).

Operation is divided into regular periods, usually a year, with further subdivisions by months or shorter intervals. Within each accounting period, the various fiscal changes are recorded as the transactions take place. Each account is debited or credited as it may be affected. At the close of the period, each account is balanced so as to show its net status at the particular time. For each asset account, all the debits are added; the sum of the credits is deducted from the sum of the debits, leaving a net debit balance as the book value of the particular class of property. Likewise in respect to any liability or source account; at the close of each accounting period, the sum of the debits is deducted from the sum of the credits, and the balance is a net credit for the particular source or interest in the business. These balances are then brought together in a balance sheet, which, under recognized American practise, presents the assets on the left side, according to the classification employed, and the liabilities on the right side, classified according to various sources or interests. The balance sheet thus presents, at the close of each period and for the beginning of the next, the financial status of the business.

During a period of operation in between balancing, it is necessary or convenient to introduce special or temporary accounts to record the transactions. In a large business, these accounts include elaborate classifications of purchases and sales, operating expenses and revenues or manufacturing costs and trading, all pertaining to the particular period. All these interim accounts, however, record only such fundamental changes as above explained, and serve merely for the convenience of periodical calculation. At the close of each period, all these accounts are brought together and are presented as an income statement (or profit and loss account, or under some other title). The net results show the net profits or losses of the period; they are then carried to the

balance sheet, which shows the extent to which the assets were derived from past profits of operation (or the extent to which assets were dissipated by past losses of operation).

The accounting system thus requires a classification according to the purposes of the business, not only of the various asset accounts and the various sources of the assets, but also of the periodical processes of operation. For merchandising, this involves a coordinated group of purchase and sales accounts and inventories, together with the wages and materials and other expenses connected with current operation. For a manufacturing concern, it includes systems of cost-keeping to show for each period the costs of the commodities produced.

A great deal of public attention has been given to the accounting systems of railroads and public utilities. For such purposes, elaborate classifications of operating expenses have been established to show the various costs incurred during each period in respect to the services furnished for which revenues are collected or accrued. So far as principle or accounting technique is concerned, there is no fundamental difference from the operation of merchandising or manufacture. Operating expenses represent charges or debits to individual accounts for cost of service instead of cost of commodities. For the service rendered, the revenues are accrued and collected. At the close of each period, the operating accounts are brought together in appropriate groups, as an income statement, to present the results in the most desirable form for the management and the public. The net returns (or losses) are then carried to the balance sheet, and are presented as in any other form of business.

The classifications for railroads and public utilities have particular significance, because of the special public interest in such properties. These are concerns distinguished from ordinary business, in that they are vested with public rights and are particularly subject to rate regulation by public authority. Rates must be reasonable, and, for the most part, the measure of reasonableness is the cost of service, including a fair return on the property used in operation. While other considerations enter into the determination of rates, an accurate record of costs is essential. There is, thus, a special public significance in railroad and public utility accounting. For the most part the systems now in use have been prescribed by the commissions

and have the force of law for the companies. The Interstate Commerce Commission has elaborate railroad and other classifications, as to property, balance sheet accounts, operating expenses, revenues and income accounts. Uniform systems for the various utilities have been prescribed by several state commissions. The purpose of all such classifications is to determine the cost of service, including the separate cost of every important phase or function of operation.

In all such classifications, it is important from the public standpoint, as well as from that of the management, to preserve clear distinctions between costs that are properly chargeable to asset or capital accounts, and those chargeable to operating account to be included in the determination of the cost of service for the particular fiscal period. There is, ordinarily, no difficulty in preserving the proper line of demarcation. The charges to operating expenses include all costs which belong to the service rendered during the particular accounting period. They include all labor and materials used directly in operation; in the case of railroads, for example, the wages of trainmen and the cost of coal used in train movements; in electricity, the powerhouse labor and fuel; for gas, the cost of labor, coal, oil and other materials used for gas production. These are all costs that are directly identified with the service supplied, and are properly included in operating expenses of the period.

Operating expenses, however, include not only all such direct labor and materials used in service, but also the cost of maintaining the property, together with the depreciation chargeable to the particular accounting period. The object is to keep the net property accounts intact; to include in operating expenses all such charges as will preserve the net investment in the fixed capital of the utility, and to add to capital account only improvements and extensions to the property. In regard to maintenance and depreciation, there is greater difficulty in preserving the distinction between proper charges to capital and to operating account.

The established policy is to charge all repairs and minor renewals of property to the operating expenses of the accounting period. True, for strictly accurate accounting there should be separation between periods, because repairs made in any one period are usually due to operation of prior periods; in practice, however, such classification is not feasible. For the most

part also, there is an equalization of such costs from period to period, so that the expenses are presented usually with reasonable accuracy in relation to the service rendered. Moreover, to avoid variation in operating expenses from one period to the next a number of periods are usually considered when it is desired to establish the normal cost for the purposes of rate control or executive decision.

The difficulty referred to in respect to repairs and minor renewals appears especially in regard to depreciation or the allowance for the renewal of major units of physical property used in service. While repairs, including the renewal of all minor units of property, tend to equalize themselves, there is much greater variation in renewals from period to period for the larger or major units of property. To charge the cost of all such renewals directly to operating expenses, would result in material distortions and would not be satisfactory for either administrative or rate-making purposes. To prevent this inequality, the so-called depreciation policy instead of the direct renewal costs, has been employed in determining the charges to operating account. The cost of any unit of property with a limited lifetime must, in any case, be finally included in the cost of operation by the time it is replaced. The method of depreciation distributes or allocates to operating expenses the cost of any such unit during its lifetime in service. If an article is consumed or used exclusively during one period, its entire cost belongs to operation of that period. If it be used for a number of periods, its cost must be divided between the periods on the basis of relative use.

Railroads and all public utilities, as well as large industrial plants, consist of huge operating properties the individual units of which have varying years of service. In respect to all such units, the capital cost must be replaced through charges to operating expenses, and thus included in the stated cost of service. For strict accounting, it is necessary therefore to make separate provision for each major unit. Schedules of property must thus be made, showing the unit costs, the expected life and the annual charge for depreciation. The last two items are estimates based upon experience and expert knowledge of operations; still the actual life or total serviceability of a unit of property may turn out to be at considerable variance with the estimate. The management must, therefore, keep in constant touch with the properties,

and should be prepared to modify the estimates as the conditions require.

The usual accounting procedure is to charge depreciation to operating expenses for each period, and to credit the amounts cumulatively to the depreciation reserve, which appears as a credit item in the balance sheet. As actual physical units are retired, their original cost is credited to the property account and charged to depreciation reserve, with adjustments for salvage; the cost of renewals, as of all new property installed, is then charged to the appropriate property account. With this general plan, the sum of the balances of all the property accounts at any time shows the original cost of all the properties then in use, while the balance of the depreciation reserve shows the amount of such costs that have been allocated to past operating expenses as depreciation, and included in the cost of service. The difference between the sum of the property accounts and the depreciation reserve is the net property cost applicable to future operation, to be provided for through subsequent depreciation charges included in future cost of service or output.

While depreciation is usually credited to and accumulated in separate reserves, which are required by most of the official accounting systems, the credits might be made directly to the property accounts, with the same net results in the allocation of costs between capital and operation. If such direct credits were made to the individual property accounts, the balances from time to time would show the net cost after depreciation, instead of the original cost of the property left in service. The setting up of depreciation reserves is preferable, because it furnishes more complete records. It preserves the cost of all properties in use; shows periodically the cost of properties retired, and presents in a single figure the amount of depreciation provided for on account of properties left in use.

The Interstate Commerce Commission has required detailed depreciation provisions for each class of equipment, and for the individual units in each class. It will extend the same general requirement hereafter also to the road accounts, without extending it to the individual units since they cannot be as readily individualized as the items of equipment. The classifications prescribed for utilities by the state commissions impose much less detailed treatment. For the most part, the state commissions have merely the right to prescribe uniform

systems of accounting, including the accounts for systematic allowance for depreciation; but they have not had the power to compel the companies to make proper charges for depreciation. As a result, there is wide variation in practise, and the experience to date has been of little value for rate making purposes or for executive control of the properties. Every important rate adjustment has required a separate inquiry as to depreciation, without regard to the provisions actually made by the company through its regular accounting procedure.

Satisfactory administration of rate making largely depends upon the adoption of a systematic cost system. As yet, however, accurate cost accounting in relation to property, maintenance and depreciation, is not accepted as even the controlling factor in fixing rates, and for that reason principally regulation has not been as satisfactory from the public standpoint as had been expected. Effective regulation depends upon definite standards and upon exact facts not subject to dispute. The existing system, where it is not based upon costs, arouses conflict of interest between the companies and the public, and thus results in litigation instead of mere administration of rate making policies.

Apart from regulation and the enforcement of a public interest in property or business, the question of valuation of business properties for accounting purposes has received a vast amount of discussion among accountants and analysts interested in accounting data. One group insists that all the accounts must rest strictly upon monetary costs, both as to property and as to charges to operation or manufacturing output. The second group agrees that all operating expenses, and all direct labor and material charges conveyed to manufacturing costs, should be based upon cash expenditures. As far as property accounts are concerned, however, the latter holds that the amounts should be revised from time to time to bring each account in conformity with the actual conditions of the business at the time of the balance sheet. If property values have risen or fallen, the fact should be recognized in the accounts and in the corresponding showing of the balance sheet of the business.

Apart from public policy or individual business expediency, there is little fundamental principle in the issue thus presented. If there is a special public interest in a business, the rights of the public should be clearly expressed

and safeguarded through the accounting and business records. The public interest thus determines the basis of valuation that should be adopted for public purposes. Where there is no special public interest, the private business purposes must determine the policy to be carried out through the accounts.

All purchases, expenditures, sales and revenues are recorded, in the first instance, at the actual monetary consideration at the time of the transaction. In regard to this practise, there is no difference of opinion as to desirability of procedure. There must be accurate original records of the transactions that actually take place. Subsequently, so far as the property accounts are concerned, it is a matter of expediency, of wise business administration, whether the original costs shall be continued, notwithstanding fundamental changes affecting the industry, or whether a revaluation shall be made from time to time. If the original costs are retained, then the accounts will show constantly actual cost records as to property; such records are of themselves desirable and important to the management. If, however, conditions have changed materially, such records carried into the balance sheet would be misleading as to the showing of financial standing. The property may be grossly understated or overstated as compared with the reasonable value at the time of the balance sheet. The statement of surplus would merely represent the result of the annual accounting as carried into the balance sheet, and would not be based upon the actual values contained at the time in the business. The balance sheet may be intended on the other hand primarily to present a cost statement as to properties in the business and their sources, or to set forth as correctly as possible the real property values and the actual relative rights of the various interested groups. Neither purpose can be taken as fundamental and controlling. Each may be carried out consistently; both may be represented by two different sets of statements. The important consideration is that the objective is clearly conceived, and that the facts are accurately presented accordingly.

The basis of valuation with changing fundamental conditions has a bearing also upon the statements of operating expenses, or manufacturing costs, and the computation of annual profits. In regard to depreciation, for example, shall the charges to operating expenses or to manufactured products be based upon the

original money cost of plant units, or upon the market value of similar property at the time of the operation? A consistent cash system would hold to original cost; but if the level of property costs has materially changed since the particular units in use were installed, such a basis for determining depreciation charges, while presenting accurate cost records, would fail to furnish a desirable guide to sales policy under prevailing conditions. What is to be done depends upon the purpose of the management, and not upon inflexible principles of accounting. Depreciation charges may be based quite properly upon revaluation or expected renewal costs rather than upon original costs of the properties. Likewise any accounting entries may be validly changed with shifting conditions in the business. It is important, however, that the purpose be clearly established and that the character of the accounting be correctly presented.

The basis of accounting adopted finally affects the computation of annual profit shown by the business. If original cost is rigidly adhered to, the showing of annual profit and the accumulated reserves and surplus would all reflect cash cost and disregard the changes in values that may have affected the business. A depreciation reserve thus established may be excessive or inadequate for the physical renewals of property. A surplus thus accumulated may have no relation to the actual value attached to the ownership of the business. The accounts, however, would state the facts of cash costs incurred by the business. If periodical adjustments are made according to changing conditions, they would affect, in the first instance, the property values, and would then require a redetermination of reserves and statement of surplus. If property values are materially increased, the depreciation reserve would have to be augmented proportionately with the higher level of expected renewal costs, and surplus would be increased according to the higher showing of net property values. Neither reserve nor surplus as stated in the balance sheet would thus be identified with the periodical depreciation accruals and the statements of income. But if the revaluations are properly made the results would reflect the actual financial standing of the business at the time of the balance sheet.

In this matter of valuation, there is also finally involved the item of good will, so far as private business is concerned. If the object is to present financial standing, the total value

would be materially affected by the character of the management, location, business connections and other facts, which, taken together, determine the good will of the business. A complete present statement would include, first, the physical properties valued on the basis of costs at the time of the balance sheet, plus the good will valued according to earning power in excess of the return required to support the physical properties. There is often little significance in the valuation of physical plant, especially where this consists of fixed properties which can be used only for the particular business. The ultimate basis of plant value is financial success, and the stated physical values may be inadequate or excessive in relation to established earning power.

These considerations lead to calculation of intangible values, as distinct from the physical properties subject to independent appraisal. Accountants, generally, are opposed to including intangibles which are based upon earning power, even if they favor revaluation of physical properties. If the purpose, however, is to show actual financial standing, the showing is manifestly incomplete if it presents merely physical properties and not the actual values of the going concern. As to the various purposes and policies, accountants tend to conservative positions; and, for the most part, hold that the purpose of accounting is to show costs, and not values. They argue that costs represent actual cash outlays which are accurately reported and can be definitely carried out through the entire system of accounts, both in respect to the allowance for depreciation and all charges to operation and manufacturing output, as well as in respect to property and source accounts shown in the balance sheet. If it were desirable to show values, they would make a separate determination which would set out independently of the accounts not only the physical values, but also the good will (or opposite) dependent upon earning power, and would present the reserves and surplus accordingly. Such showing, however, they would not incorporate with the regular accounting procedure, but would preserve as separate records.

In conclusion, it is important to emphasize that accounting has to do with fiscal records, and that all policies and methods depend upon the purposes to be achieved. In the first place, there is the distinction between properties affected with a special public interest and those not so affected. As to the first group, the ac-

counting system must be based upon the character of the public interest, and upon the objects to be attained through regulation. In private business not affected by public interest, the accounting follows the purposes of the management; this applies particularly to the adjustments in values made subsequent to the recording of original transactions. The first records must, of necessity, represent what was actually done. What changes are made subsequently, depend upon the purposes of the management. The conceptions to be carried out must be clear, and the corresponding records must be kept accurately.

Accounting is an instrument of public policy and of private management; it is adaptable to any purpose and any condition. It is not a set of fixed rules or unbending principles to be followed without regard to public or business objectives. It is essential for public and private purposes, and it is a means for their achievement.

ACCOUNTS, PUBLIC, may be said to be almost as old as organized government. Of course in the ancient days they were very rudimentary in character. For almost two centuries after the earliest printed work on book-keeping, which was written by a monk, Luca Paciolo, and published first in Venice in 1494, such development as took place in accounting (if it may be dignified at that period by the

use of this term) related mainly to the requirements of business and commerce. Perhaps the first real attempt to bring the accounting methods of government abreast with those of business was made by Colbert under Louis XIV of France during the latter part of the seventeenth century. By the end of the eighteenth century England had begun to develop a national financial system which laid considerable emphasis on the accounting features. This system was finally established on its present basis by the Exchequer and Audit Act of 1866. In the United States public accounting did not receive much attention until the opening of the twentieth century. Its development has been greatly stimulated by the movement for budgetary reform during the last two decades.

Before the introduction of budgetary methods in the United States, public accounts provided little more than a general record of financial transactions and served mainly as the means of enforcing, within certain limits, the provisions of law with respect to appropriations. They did not furnish the type of information that the executive needed in directing administrative work or that the legislative body might use in determining the fiscal policies of the government. But this situation has been considerably improved during the last twenty years. The accounting systems of several of our governmental units now comprehend all financial transactions and produce information relating thereto with promptness and accuracy. They provide, to some extent at least, the necessary data for planning and executing the government's work, thus serving, as they had not done before, the purposes of day-to-day administration.

Public accounting has been influenced in no small degree by the methods and practises followed in commercial accounting. In fact efforts have been made to carry the essentials of commercial accounting directly into government accounts. The capital balance sheet, for example, has thus been made a part of the accounting system of many governmental units. Perhaps this tendency has been due to the fact that oftentimes the responsibility for installing a system of public accounts has fallen upon accountants who were experienced mainly in commercial work and who did not fully appreciate either the scope or the financial requirements of government.

The purpose of a government is quite different from that of a business concern. The
